Much more, however, is done than merely feeding and clothing the children. There is the all-important question of medical inspection and treatment. The schools of the city of Brussels are divided into six groups and each group has its medical officer. In normal times all the kindergartens, the crèches, and the classrooms devoted to primary education must be medically inspected twice each month. The classrooms for secondary education or technical education need be visited but once a month. In each class-room there must be a thermometer and a written record kept of the temperature and this must be countersigned by the medical officer. He must also examine the pupils from the physical and intellectual point of view and endeavour to foresee and to check any abnormal development or tendency to disease. What is qualified as "preventive medicine" (prophylactic), such as cod-liver oil, may then be prescribed at the public expense. A remarkable feature of this medical service is that the medical officers have to give lessons on hygiene to the senior classes—namely, children about 12 years old. At the beginning of each month they must deliver a simple lecture or explanation. Then the pupils must write an essay to show that they have understood what they have heard and the medical officer looks over these essays and repeats on the next occasion what the essays show has not been fully understood. The following are the subjects which the medical officers have to explain and to lecture upon: (1) cleanliness of the person, the clothes, and domestic utensils; (2) the house, its cleanliness, the dangers of damp, the soil, the building materials, and plan of dwellings; (3) air, foul air, and ventilation; (4) water, when pure, when polluted, boiling and filtration, use and abuse of water; (5) heat, fuel, and warming apparatus clothes and boots; (6) light, artificial and natural; (7) food, what constitutes wholesome food, adulteration of food; the moral, intellectual and physical degradation caused by alcoholism; (8) the excretions, care of the skin, mouth, hair, sight, and hearing; (9) exercise, work, play, gymnastics, and rest; (10) accidents, first care in cases of wounds, sprains, hæmorrhage, and poisoning; and (11) contagious and infectious diseases, prophylaxis, and disinfection. For primary schools this seems a fairly complete curriculum and if the pupils apply these lessons to their home life a very considerable and all-round improvement should result.

In regard to infectious disease when a child is absent from school the parent receives a letter inclosing a post-card, with printed questions about the child which he must answer and post. If the child is detained because of infectious illness the Bureau of Hygiene is at once informed and all children living with the patient are forbidden to go to school till after disinfection. The disinfection, of course, follows on the removal of the patient to the hospital or on death or recovery. Vaccination is not obligatory but during the year 2489 out of the 13,994 children were revaccinated, and this is a good number for revaccination is not offered till the children are nine years old. Apart from vaccination, "preventive" treatment was given to 3860 children out of the 13,994 and 3929 children were found to have defective teeth. Of these latter, 2251 presented themselves for treatment by the surgeon-dentist employed by the municipality to look after the school children. From the ailing or delicate children, 785 were selected and sent at the cost of the town either to the country or to the seaside where attending to my business I discovered that was simply because I had not fulfilled the conditions of success.

I have no doubt but that Mr. Hilliard's instrument is an admirable one and I regret that I must say—judging from his lucid description and the picture accompanying it—I prefer something I can easily hold in my hand to an inhaler fixed on a board which has to be fixed under the mattress; something I can hang up near me to an instrument that needs a table for its accommodation; something that by its "click-click" tells me the respirations are all right and at a glance that oxygen as well as chloroform is reaching the lungs. For, as he truly says, "chloroform can never be quite safe." Is anything quite safe ever in excess? I am, Sirs, yours faithfully,

DAVID ANDERSON-BERRY, M.D., F.R.S. EDIN.

THE USE OF PHENYLHYDRAZIN IN THE EXAMINATION OF URINE.

To the Editors of THE LANCET.

SIRS,—I regret having overlooked the point to which Dr. P. J. Cammidge refers in THE LANCET of July 29th, p. 316. In his article in your issue of July 1st it certainly seemed to me that he was advocating the rapid method of using this test. I am aware that operating with aqueous solutions is not quite the same as is the case with a urinary solution, but even in this latter case I find that if 0·3 gramme of maltose or lactose be dissolved in 100 cubic centimetres of normal urine and the phenylhydrazin test be then applied, an appreciable deposit of osazone crystals results if the water bath be used, whilst boiling over the free flame for five minutes elicits no response at all. With regard to dextrose I have repeatedly found that if the urine contained but a very small quantity a positive reaction could almost invariably be relied on after 30 minutes of the water bath, but this was by no means the case with the rapid method. Further, I have had the same experience when using Dr. Cammidge's own test for pancreatic urine.

I am, Sirs, yours faithfully,

L. C. S. BROUGHTON.

Langley-green, Birmingham, July 31st, 1905.

TEMPORARY FIXATION OF AN IMPERFECTLY DESCENDED TESTIS TO THE THIGH.

To the Editors of THE LANCET.

SIRS,—I have read with much interest Mr. C. B. Keetley's further account of his procedure as given in THE LANCET of July 29th, p. 279. I have no doubt whatever that an imperfectly descended testis has, in the great majority of cases, some value. If it lie within the abdominal cavity I believe it has a greater value than if it has been arrested in the inguinal canal or high in the scrotum. Seeing that one has so constantly to operate for the hernia, potential or actual, which is nearly always present, what should be done with the retained testis is a matter of moment. If it is of value it should not be removed. If it can be brought down into, and *kept* down in, the scrotum this has undoubted advantages. But there are very few cases in which this permanent position is attained. Mr. Keetley does not state in how many it occurred in his 25 cases, but merely "the testis generally remains permanently in the scrotum but near its root." I am not sure what is meant by the "root of the scrotum," but I am sure that a testis placed at the level of the root of the penis is little if at all better off than one in the inguinal canal. Again, Mr. Keetley asks the question, "Do these testes grow when brought down in the scrotum?" and he answers, "Undoubtedly some of them do but not to the size of normal testes." Again, he does not give numbers, and accurate statistics are what is needed on this interesting question. I, personally, have never seen a testis *increase* in size after being artificially brought one inch or so lower down—that is, into the upper part of the scrotum. If any have done so I do not believe that their forcible displacement has had anything to do with their subsequent enlargement. On the other hand, I have seen many testes both in my own practice and in that of other surgeons *diminish* in size after being pulled down. Further, I am at variance with Mr. Keetley when he says that a testis just below the superficial abdominal ring—that is, just below the inguinal canal—is in a comfortable position. My experience is that testes which have reached this position naturally, but have been arrested there, are very apt to be drawn up at times against and through the pillars of the opening, whereby much pain is caused, and that even when no actual hernia exists. To fix a testis artificially here is to leave it subjected to these pulls during the movements of the abdominal muscles and to leave the patient liable to intermittent suffering. Mr. Keetley has been fortunate not to come across such a condition. I have and have had several times to remove the testis for it. But if the testis is of value and cannot be satisfactorily brought down and should not be removed there is still another procedure which may be adopted. This is to return it, after it has been freed if necessary, within the abdominal cavity. I have never regretted doing this. The testis is placed, like the ovary, in a comfortable position, the inguinal canal can be completely closed, and there is only a mythical increased tendency for it to become the site of malignancy. I find more and more surgeons are adopting this simple method and with the most gratifying results.

I am, Sirs, yours faithfully,

Harley-street, W., July 29th, 1905. W. MCADAM ECCLES.

THE TREATMENT OF FRACTURED RIBS.

To the Editors of THE LANCET.

SIRS,—The treatment of fractured ribs by strapping is probably less satisfactory to the patient than to the surgeon. From personal experience it seems so to me. When in South Africa I had three ribs and a shoulder-blade fractured. I was well strapped in routine fashion but was relieved for a short time only, the strapping only too soon becoming loose. Pain prohibited me from lying in bed, doubtless owing to the fractured shoulder-blade, at that time not diagnosed. It then occurred to me that fixation by something resembling a stays would be an improvement upon the old method. A simple binder on these lines made of stiff jean I had made, fitted to lace up at the back and tie in front. Shoulder bands (of tape) also to tie at convenience kept the binder in position. The objection naturally raised to this treatment would be that it was a restraint not only on the injured but also on the uninjured side of the chest and calculated to interfere with the breathing. As a subject of spasmodic asthma from early childhood I can only say that it does not appear to be so. The relief obtained from the home-manufactured stays was enormous and I had no dyspnœa. As far as the ribs were concerned the treatment was entirely satisfactory.—I am, Sirs, yours faithfully,

FRANK ELVY, M.R.C.S. Eng., L.R.C.P. Lond.

Broadwindsor, July 31st, 1905.

FREE MEALS, CLOTHES, AND MEDICAL TREATMENT FOR THE SCHOOL CHILDREN OF BRUSSELS.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

Brussels, July, 1905.

THOUGH the agglomeration of independent boroughs which is called Brussels is very small as compared to the metropolis of London, the city of Brussels is very much larger than the City of London. The *agglomération Bruxelloise* may count some 600,000 inhabitants, a third of whom live in the city of Brussels itself. It is not a third or even a thirtieth part of the inhabitants of the metropolis that live in the City of London. In any case, whatever the historic city of Brussels has done is a matter of importance throughout Belgium and often serves as an example for the whole nation. In view of the physical degeneration of certain sections of the population not only in England but in all industrial countries, and of the fact that on all sides there is a very general conviction that better care must be taken of the children in the primary schools, I have made some inquiries as to what has been done here. Unfortunately for many years Belgium has been distracted by a fierce conflict for and against clericalism. The cause of education has consequently suffered greatly. There are two sorts of schools—the "free school," managed by the priests, and the communal school, managed by the municipalities. About the latter every possible information is forthcoming; every farthing spent is accounted for and vital statistics are forthcoming so that some information is at hand in regard to the health of the pupils. As for the free schools, the less said about them the better pleased are those who are interested in their maintenance. It is only when infective disease exists among the pupils that the authorities have a right of entrance to these schools and this right is derived from the laws which the French Republic established in Belgium in 1793. In such circumstances the only information available that would be of use for anything like a scientific investigation is that supplied by the local authorities concerning their own schools. Education in Belgium, though widespread, is not universal and there are still a good many children who do not go to school at all. This is notably the case with girls who are frequently kept at home to help in the household work. Nevertheless, in the primary schools of Brussels much the same problems arise as those which have puzzled the education authorities in London and all the great industrial centres. It is evident, in Brussels as in London, that a certain number of children are insufficiently fed and are wanting in clothes, while others are absolutely deficient in health, stamina, and mental and physical development. It must further be recorded that in spite of the gravity of such a state of affairs no very heroic remedy has been attempted. Nevertheless, a good deal of steady work has been done, though reforms were introduced gradually and in detail and there has been no sweeping and sensational legislation.

A peculiar feature about such attempts as have been made is the fact that whereas in England the cry that the children must be fed has gone forth with swelling strength and volume, in Brussels it would seem as if greater attention is bestowed on the necessity of clothing the children. In any case the official reports show that during the school year 1903-04 the number of children frequenting the communal schools of the city of Brussels for primary, secular, and gratuitous education amounted to 13,994. From Nov. 16th, 1903, to March 26th, 1904, these children received 318,699 helpings of soup and 307,609 rations of bread. This was not given to all of the children but to 2691 out of the number or, roughly speaking, to one out of every five children. So that this might be done the municipality of the city of Brussels gave a subvention of £400. It also gave a soup subvention of £200 to the free schools—that is to say, to the clerical schools. It should further be mentioned that 679 little children attending kindergarten schools were likewise fed. On the other hand, and during the same year, no less than 2107 complete suits of clothes and 14,580 various articles of clothing were given to 7963 pupils attending the communal schools. Thus, putting the matter in round numbers, one out of every five children was assisted with gifts of food and one out of every two children with gifts of clothing. This is certainly very different from what is in contemplation in England where the question of clothes has scarcely been raised. A number of different charities and committees work to collect some of the money necessary to provide these clothes. Then when fairs are held the municipality charges the holders of booths, stalls, &c., a certain rent. A portion of the money thus received is devoted to the purchase of clothes for the school children. Moreover, the municipality supplies at the public cost raw material to the schools and the children are taught sewing, dressmaking, tailoring, and so on, by converting this material into clothes. In this manner 146 suits and 6771 different articles of clothing were made by the children themselves and were given to those among them who had need of these things. During the year various private charities supplied 1582 complete suits and 5428 articles of clothing, while 525 suits and 13,796 different articles of clothing were given by the municipality, that is to say, at the public cost. Still more was done for the little children who frequent the communal kindergartens. There are 3365 children inscribed and the average kindergarten attendance was 2848. Among these children private charity gave 218 suits and 2486 articles of clothing and out of the public purse they received 91 suits and 4224 articles of clothing. Private charity also distributed 3850 toys and 2649 gifts of sweets or of fruit to the kindergarten children. It cannot be said therefore that they have been neglected.

Perhaps the fact that the need of clothes is apparently greater than that of food may be due to the more orderly and economical disposition of the Belgian poor. Belgian women have more knowledge and skill with regard to their housekeeping than would usually be the case with a similar class of poor in England. It will then be easily understood that a well-ordered family, living on from 16*s.* to 20*s.* a week, may be able to give regularly the few pence daily required for each child's food but cannot afford an occasional outlay of several shillings to buy clothes. The parents might justifiably prefer to give sufficient food rather than to save money for the purchase of clothes. Thus in a well-kept household poverty manifests itself by the want of clothes rather than of food. This is possibly the reason why in Brussels more has been done in regard to clothing than to feeding the children. Doubtless if this clothing was not given and the parents were forced to spend the little money that they have in buying clothes, there would be more starvation among the children and consequently more food would have to be provided. So that the result would be somewhat similar in the long run.

Much more, however, is done than merely feeding and clothing the children. There is the all-important question of medical inspection and treatment. The schools of the city of Brussels are divided into six groups and each group has its medical officer. In normal times all the kindergartens, the crèches, and the classrooms devoted to primary education must be medically inspected twice each month. The classrooms for secondary education or technical education need be visited but once a month. In each class-room there must be a thermometer and a written record kept of the temperature and this must be countersigned by the medical officer. He must also examine the pupils from the physical and intellectual point of view and endeavour to foresee and to check any abnormal development or tendency to disease. What is qualified as "preventive medicine" (prophylactic), such as cod-liver oil, may then be prescribed at the public expense. A remarkable feature of this medical service is that the medical officers have to give lessons on hygiene to the senior classes—namely, children about 12 years old. At the beginning of each month they must deliver a simple lecture or explanation. Then the pupils must write an essay to show that they have understood what they have heard and the medical officer looks over these essays and repeats on the next occasion what the essays show has not been fully understood. The following are the subjects which the medical officers have to explain and to lecture upon: (1) cleanliness of the person, the clothes, and domestic utensils; (2) the house, its cleanliness, the dangers of damp, the soil, the building materials, and plan of dwellings; (3) air, foul air, and ventilation; (4) water, when pure, when polluted, boiling and filtration, use and abuse of water; (5) heat, fuel, and warming apparatus clothes and boots; (6) light, artificial and natural; (7) food, what constitutes wholesome food, adulteration of food; the moral, intellectual and physical degradation caused by alcoholism; (8) the excretions, care of the skin, mouth, hair, sight, and hearing; (9) exercise, work, play, gymnastics, and rest; (10) accidents, first care in cases of wounds, sprains, hæmorrhage, and poisoning; and (11) contagious and infectious diseases, prophylaxis, and disinfection. For primary schools this seems a fairly complete curriculum and if the pupils apply these lessons to their home life a very considerable and all-round improvement should result.

In regard to infectious disease when a child is absent from school the parent receives a letter inclosing a post-card, with printed questions about the child which he must answer and post. If the child is detained because of infectious illness the Bureau of Hygiene is at once informed and all children living with the patient are forbidden to go to school till after disinfection. The disinfection, of course, follows on the removal of the patient to the hospital or on death or recovery. Vaccination is not obligatory but during the year 2489 out of the 13,994 children were revaccinated, and this is a good number for revaccination is not offered till the children are nine years old. Apart from vaccination, "preventive" treatment was given to 3860 children out of the 13,994 and 3929 children were found to have defective teeth. Of these latter, 2251 presented themselves for treatment by the surgeon-dentist employed by the municipality to look after the school children. From the ailing or delicate children, 785 were selected and sent at the cost of the town either to the country or to the seaside where they enjoyed between them 9945 days of pure air, or rather more than an average of 12 days for each pupil. In this respect private charity ran a neck-to-neck race with public enterprise, for various charitable societies sent 798 children to the seaside or the country. But their outing was a little shorter, amounting to 8594 days in all, or an average of a little under 11 days for each child. These, of course, were the children from the free schools. Of the 785 children sent to what are known as children's colonies by the municipality only two failed to gain in weight. There can be no doubt, therefore, as to the very great amount of good achieved by these brief holidays in the open air or by the sea. Measures have now been taken to record more systematically the benefits that result. Next autumn all the children placed under special medical surveillance, or what is called "preventive treatment," and this is likely to be not far short of 4000 out of 14,000 children, will be weighed and the chest measurements will be taken. In this manner some valuable data will be collected and other improvements are likely to be effected from year to year.

According to a report drawn up for the municipality by Dr. Gaston Daniel in February, 1897, there were at that date out of 14,000 school children 2442 who were badly shod and 3620 in urgent want of clothes. Then 684 had no bed to sleep on and 2474 were insufficiently fed. These figures only deal with the communal schools of the city of Brussels and the principal difference to-day is that these wants are better provided for. Nor must it be thought that the surrounding boroughs are neglecting these questions. For instance, the outlying district and borough of Anderlecht, which has a population of 55,002 inhabitants, has decided to provide a complete midday meal. All are to be admitted, even the pupils from the free schools; the only condition is that they must dine in the communal building. It is estimated that the meal will cost from 1½*d.* to 2*d.* The charge in any case will be 2*d.* and it is hoped that a slight profit will be made on this so as to help to defray the cost incurred for those who cannot pay. Tickets will be given to the children and great care taken not to let it be known who are those who can afford to pay. Above all, no child is to be exposed to any sort of humiliation. The municipality of Anderlecht will pay for these meals; no school child will be refused the food which he needs. If some of the outlay can be recovered from the parents this will ease the public burden but whatever happens the children must be fed. From all this it will be seen that the inhabitants of the city of Brussels and the neighbouring districts are moving forward. Philanthropy and private charity have done a good deal but this is all too uncertain and unequal in its effects. It is a useful help to municipal effort but it needs to be regulated, systematised, and evenly distributed by the municipal authority. Thus it is that the part played by the municipalities daily increases in importance.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Death from Anthrax.

THE occurrence of anthrax in our cattle is becoming so common that it suggests ignorance or carelessness and a relaxation of the vigilance which against such a foe should be constant but seems apt to slumber. But, as if this danger were not enough, there is the never-ceasing risk run by those engaged in cutting and sorting foreign rags and in handling foreign hides, &c. An inquest was concluded on July 25th by Mr. P. P. Maitland, the West Riding coroner, on the body of a girl, aged 16 years, concerning the cause of whose death there was for a time some doubt. It was alleged that she contracted a disease while cutting and sorting some foreign rags at the warehouse of a firm of rag merchants at Dewsbury so far back as a little before Easter. At the opening of the inquest it was stated that the girl, previously strong and healthy, had become subject to boils on the hands and that "a virulent abscess formed in the right armpit." A post-mortem examination was made by Mr. A. E. Sellers of Thornhill, near Dewsbury, who found abundant evidence of tuberculosis but was unable to detect the existence of anthrax. Some portions of the viscera were sent to Dr. J. R. Kaye, the medical officer of health of the West Riding, for examination and he stated in his evidence that in the lungs, which were highly tuberculous, he had found anthrax bacilli in great numbers, and that anthrax existed and was the cause of death. The verdict of the jury was that the girl died from anthrax while suffering from tuberculosis. It would be well if all wool, rags, or hides from infected countries were either carefully examined microscopically, sterilised by superheated steam, or in some way made safe for those who have to get their living by working among them. Even if all the avenues of approach were not protected some of them would be. No doubt the ignorance of farmers, butchers, and others who may come in contact with infected matter makes thorough supervision difficult, but it is not too late to attempt a more efficient safeguarding from anthrax than exists at present.

Oldham Imbecile's Death.

One of the unfortunate cases that occasionally occur to disturb the public mind as to the treatment of imbeciles in workhouses and asylums was inquired into at Oldham on July 21st. A man was admitted to the Oldham workhouse on July 23rd, 1904, and to the imbecile ward on August 3rd following, when he had no injuries. On June 29th this year he was found to be suffering from a dislocated shoulder, which was also extensively bruised, the jaw was swollen, and there were bruises between the shoulders. These injuries seemed quite recent. The man was very seriously ill besides suffering from softening of the brain, to which condition death was attributed. The attendants expressed surprise at the man's state and the head attendant said that he could not account for the bruises. At times the patient was stated to be quite vicious and during the night before his death "there must have been something unusual as a portion of the bedding had been displaced." Two other attendants were closely questioned but "failed to give any information." The jury were not satisfied with the evidence and the inquiry was adjourned. It is evident that in some way considerable violence was used by someone and the mystery should be cleared up.

To Live a Century.

Among the many picturesque utterances of Sir James Crichton-Browne few have attracted more attention than that of his belief that "every man is entitled to live a century." So much is this the case that the medical officer of health of Manchester has actually been "interviewed" on the subject by a representative of one of our daily papers. Dr. J. Niven appears to have expressed his views with frankness, conditioned by a certain caution which is rarely wanting in those whose privilege it is to have been born north of the Tweed. He was disposed to agree with the general tenour of Sir James Crichton-Browne's speech, and was not prepared to deny "that a century of healthy life could be attained in health and vigour," nor "that given favourable conditions and barring accidents this was the normal duration of man's life." Excessive worry and the continued irritability associated in recent years with the business life of our large towns no doubt reacted on the nervous system with disastrous results. Composure of mind, well-ordered and regular habits, on the other hand, formed the best basis for a sound constitution. Dr. Niven was of opinion that with regard to the statement "that regular employment must be secured and poverty diminished," that this very considerable problem involved, among other things, the question of education. He would secure to every youth "a thorough knowledge of at least two trades," presumably on the principle of two strings to the bow. How this desirable state of things is to be brought about, even with Government aid, was not indicated. Why Sir James Crichton-Browne, or Dr. Niven, or any of the various lookers into the future should fix on a century as the normal duration of human life is not apparent. Being liberally minded as to time they surely might have allowed man as long a life as that of the tortoises of the Galapagos islands. These creatures show the great advantage of a quiet contemplative life to those who wish to attain the length of days which we are told on good authority is "normal" for man when duly qualified and conditioned.

The Whalley Asylum Inquiry.

Your Liverpool correspondent noticed last week the inquiry as to the suitability or otherwise of the site selected by the Lancashire Asylums Board for a great pauper asylum. There is no doubt of the great pressure on the present accommodation and the need for more, but that, of course, has no bearing on the question as to the site at Whalley being a good or a bad one. The evidence given at the inquiry was not only contradictory on important matters where opinions might quite properly vary but also as to matters of fact. The county surveyor and architect said that the site had a good elevation and a very fine plateau, good drainage facilities, a good water-supply could be obtained, the railway was near, and "it was also possible to carry on brick-making." He had not noticed any offensive smell from the river Calder and was not aware that sewage entered the river. He had not seen fog on the land, and so far as he could ascertain it had only been flooded twice in 40 years. Dr. F. P. Sarjant, the county medical officer of health, said that statistics showed that the death-rate of Whalley was lower than that of the county and than that of the rural district. He did not think that the health of the district was endangered by any pollution that might exist in the Calder. Professor Boyd Dawkins said that the area under consideration was covered with boulder clay of uncertain thickness but proved to be more than 40 feet thick and he was of opinion that it would be impossible to drain it so as to convert it into a perfectly dry site. He considered the Calder "an extremely filthy stream" and that it would be most improper to plant any large public institution close to the area. The prevailing south-west winds would carry whatever smell there might be. Such a situation would be the last he would choose for the erection of any institution. The Local Government inspectors had by personal inspection satisfied themselves that the Barrow Brook was "very bad." In his evidence Mr. Mould said that no asylum in England or elsewhere was built on such a site as the one now proposed. Mr. G. W. Mould, Dr. J. Dreschfeld, Dr. Martin, Dr. Gray of Blackburn, Dr. Musson, Dr. G. E. Orme, and Dr. L. T. Lancaster of Clitheroe all gave evidence as to the unsuitability of the site. Mr. I. H. Gott, a civil engineer of London, said that it was practically impossible to drain it, and Mr. E. L. Morgan, borough engineer, Bolton, said it would cost something like £18,000 to carry out a scheme of drainage which after all would not be efficient as it would not take the water between the line of pipes. Several other witnesses gave evidence of the unsuitability of the site. The application of the asylums board was for power to borrow £32,910 for the purchase of lands at Whalley for a pauper lunatic asylum for the county; this, plus the £18,000 for drainage, seems a good round sum to be spent before the foundations are begun, so that the cost, expected to be £500,000 or £600,000 by the time the building is completed and furnished, will be something to make ratepayers shudder, and if the site is so unsuitable as many well-known men declare it will be a costly and improper blunder.

August 1st.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

City Analyst of Bristol.

THE enlargement of the boundaries of the city of Bristol, carrying with it, as it does, a large increase of work, led Mr. F. W. Stoddart, who has for many years acted as city analyst, to ask for an increase in his salary of £200 per annum. Within the past few years the number of samples which he has examined has increased from 400 yearly to over 1200. It is of interest to note in this connexion that the inspector of food and drugs who takes the samples receives a salary of £300 per annum and is provided with an assistant who helps him to administer the Shop Hours Act. It would seem, therefore, that the members of the Bristol corporation cannot discriminate between highly skilled labour and that which is more or less mechanical. In May last the watch committee recommended the corporation to pay Mr. Stoddart £200 per annum for the first 400 examinations made and 6s. for each subsequent examination. This recommendation was, however, referred to the committee in order that an inquiry might be made jointly with the health committee as to the employment of an analyst who should devote his whole time to the work of the corporation, including the bacteriological investigations which have been carried out during the past two years by Professor A. F. Stanley Kent at Bristol University College. As a result of this inquiry the committees named recommended the corporation to appoint a city analyst who had been trained in bacteriological work and to pay him a salary of £400 per annum, increasing to a maximum of £600; they also advised the appointment of two assistants and a laboratory attendant and the equipment of a chemical and bacteriological laboratory. When these recommendations were before the council on July 25th an unsuccessful attempt was made to secure a continuation of the services of Mr. Stoddart upon the terms named above, and in the end the two committees were asked to reconsider the whole question, and it is understood that they will report as to the practicability of the analytical and bacteriological work being carried out in the laboratories of University College.

Crime in Glamorganshire.

At successive assizes during the past few years judges on circuit have congratulated grand juries in North Wales and in most of the South Wales counties upon the absence of serious crimes. So small has the calendar become that it has been decided to hold a joint winter assize in one county, to which will be brought the prisoners if there are any from the three counties, and if there are any civil actions they will be taken from the same areas. It is to be regretted that the county of Glamorgan cannot show such a satisfactory record. In charging the grand jury at Cardiff on July 25th Mr. Justice Phillimore referred to the very large proportion of sexual offences, no fewer than 23 of the total number of 65 prisoners being charged on that account. He recalled the fact that at the previous assizes there was evidence of some good having arisen from the religious revival but observing that many of the prisoners came from the colliery districts where the revival was very strong and very effective he feared that they had already got into the reaction.

Didworthy Sanatorium.

The second annual meeting of the supporters of the Devon and Cornwall Sanatorium for Consumption at Didworthy was held at Plymouth Guildhall on July 25th, the Earl of Mount-Edgcumbe presiding. The chairman stated that the new buildings would be completed in two weeks and that the sanatorium would then provide accommodation for 35 patients. The report showed that 49 patients had been admitted during the past 12 months. The financial statement showed that during the year the subscriptions amounted to £330, including five guineas from the Prince of Wales, and that an unfavourable balance remained. The Earl of Mount-Edgcumbe made a strong appeal for more subscriptions.

The Medical Officer of Health of Chipping Sodbury.

At the meeting of the Gloucester rural district council held on July 24th the clerk stated that he had received a letter from the Chipping Sodbury rural district council stating that they "had appointed a fully qualified medical officer of health at a salary of £30 per annum less than that demanded by Dr. Bond," and adding that "they feel justified in their action and cannot reconsider the matter." The chairman mentioned that the decision of the Chipping Sodbury council not to reconsider the matter was only carried by a majority of two votes.

(FROM OUR OWN CORRESPONDENT.)

Proposed Coöperation in the Nursing Arrangements of Hospitals for Infectious Cases.

ON the invitation of the sanitary committee of the West Riding county council a very important conference has lately taken place between 107 local authorities, 11 of these being non-county boroughs, 79 urban districts, and 17 rural districts, to discuss a scheme outlined by Dr. Kaye in reference to the supply of nurses to the hospitals under their control. In a memorandum presented in June, 1904, it was stated that there were in the administrative county 38 permanent hospitals for isolating infectious diseases, as well as about 50 for small-pox patients. The total accommodation was represented by about 2000 beds. Taking the nursing staff at one nurse to six beds their numbers would amount to about 300. The salaries paid varied from £12 to £35, so that the total salaries, excluding those of matrons, amounted to nearly £6000. It was pointed out that under the system at present in operation when an unusual number of admissions occurred at any particular hospital special nurses had to be obtained, and sometimes with difficulty, at enhanced salaries of two or three guineas per week, while at other hospitals a decrease in the number of patients caused the nurses to be temporarily in excess of the requirements. On these facts Dr. Kaye has suggested that there is room for a coöperative system among the hospitals for the interchange or transference of nurses as fluctuations occur. This would lead to efficiency and economy and would be the means of adjusting the supply of nurses to the demand in any given hospital. The scheme would depend on the voluntary coöperation of the various hospital authorities who by a representative committee would fix upon a standard gradation of nurses and their wages and uniform. Each hospital, as at present, would appoint its own staff, but every nurse on engagement would be required to sign the conditions of appointment as settled by the joint committee, to be uniformly applicable in all the federated hospitals. One of these conditions would be that the nurse undertakes to serve temporarily in any other hospital when requested by her employers to do so The scheme would necessitate the institution of a central bureau to which each hospital would send a weekly return of the number of admissions and discharges and of the number of nurses employed. The scheme appears to be an admirable one and eminently necessary in the case of hospitals for infectious cases, in which, of course, the number of patients varies so greatly and within such narrow limits of time.

Opening of the Dental Department at the Public Dispensary.

The new dental department of the Leeds Public Dispensary was formally opened on July 27th by the Lord Mayor of Leeds. The chairman of the dispensary board in introducing the Lord Mayor referred to the part which had been taken by the dentists of Leeds and district in equipping the department and complimented them on their public-spirited action in the matter. The department is situated on the first floor of the working part of the institution and consists of a series of six rooms, access to each of which is obtained from the gallery of the large out-patient hall. The rooms are all well lighted, have polished floors, and are heated by hot water coils. The ventilation is, like that of the medical, surgical, and ophthalmic rooms on the ground-floor, carried out on the exhaust system. The waiting-room will accommodate about 80 patients. The ordinary extraction room, 27 feet by 16 feet, is fitted up with two chairs and the usual fittings and instruments. The recovery room is situated between the extraction room and the operation room and communicates directly with each. The operation room is 20 feet by 17 feet, and has been fitted up with enamelled operating table, stools, instrument cupboards, &c. The chair is of the Morrison pattern, with wooden seat and back. There is a copper steriliser and the lavatory basins may be filled with shower spray, the temperature and flow of the water being regulated by a foot lever. In addition to the ordinary anæsthetic apparatus there is apparatus for the administration of "gas" and oxygen. Communicating with this is the nurses' room which will be used as a dressing-room for female patients. The conservation-room, which has roof light as well as side light, is a large room 56 feet by 20 feet and in the meantime has been fitted up with three chairs only. Two of these are of the Ash's hospital pattern and have been presented by the makers; the third is a "Twentieth Century" chair which has been presented by the Dental Manufacturing Company. The chairs are provided with combined fountain spittoons similar to those recently supplied by Messrs. Ash to the London Hospital. There are also among the apparatus a suspension chord Columbia electric engine. a Cuttriss Wallis motor, and two Parson Shaw foot engines. Electric-light brackets with universal motion are provided for each chair. In one corner of the room is a work bench fitted with a polishing lathe run from counter shafting driven by a quarter horse power electric motor and also provided with gas-fittings for blowpipes, &c. The staff consists of an honorary consulting dental officer and of six senior and six junior honorary dental officers, two of whom attend each day. The services of Dr. Capper Johnson and of Mr. Harold Collinson have been secured as honorary anæsthetists and it is confidently anticipated that the department will prove a valuable addition to the charities of the town and will supply what has long been wanted in Leeds—the clinical side of a dental school.

University of Edinburgh Graduation Ceremonial and Valedictory Address by Professor A. R. Simpson.

ON July 28th the summer graduation ceremonial of the University of Edinburgh was held, the Vice-Chancellor, Principal Sir William Turner, K.C.B., presiding. The only honorary degree conferred on this occasion was given to Mr. John Horace Round, M.A., D.L., the historian. The degree of Doctor of Medicine was conferred upon 75 graduates, including two ladies; while 155 candidates, including eight ladies, were admitted to the degree of M.B., Ch.B. Five theses were awarded gold medals. Professor A. R. Simpson, as Dean of the Medical Faculty, presented the graduates. Professor Simpson referred to his resignation, saying that in view of his age and that he had occupied the chair for 35 years he deemed it wise to resign and to hand on the torch of midwifery to his successor. He also mentioned that Professor D. J. Cunningham would succeed him as Dean of the Faculty of Medicine. He said that it was not without a pang that he resigned, because of the fact that his department became yearly more thrillingly interesting to the scientific explorer and more urgently important for the general practitioner. He then briefly referred to the enormous progress which had been made in his own department as well as in the other departments of medicine, and said that this had been attended with changes in the training of entrants to the profession. When he began to study the system of medical apprenticeship had not quite died out. Three of his fellow students had been apprenticed to the late Professor Spence, while he had had the good fortune to be apprenticed to the late Professor Goodsir. He had not in that capacity been helped much in learning to cure disease but the apprenticeship gave him opportunities for much dissection and for acquiring facility in the handling of forceps and scalpel that had been a lifelong benefit. It had brought him also under the spell of a man of genius who was a tireless toiler and who sought always what he called "God's truth." He (Professor Simpson) thought that he was himself the last of the Edinburgh medical apprentices. Professor Simpson then referred to the growth of the examination system with the disappearance of the apprenticeship system until it had become a multiplied misery. It had become a necessity because of the extension of all the subjects of study. He made a number of humorous references to his earlier days when a professor might change his chair or profess to be able to teach any subject in the university, and recalled the fact that Sir James Simpson had been urged when professor of midwifery to become a candidate for the chair of practice of physic vacant by Alison's death. He also related several very amusing experiences of his own when he was examined. As he suggested, his experiences compared with the experiences of those whom he was addressing appeared primeval and would make them realise the stupendous changes which had swept over all the fields of medicine during the intervening half century. The era spanned had been one of those "once more" epochs which the Hebrew mind had taught us to discern, when we saw the Supreme Power "shake the heavens, and the earth, and the sea, and the dry land," "that those things that cannot be shaken may remain." He said: "I do not know in what mood of pessimism I might have stood before you to-day had it not been that ere the dew of youth had dried from off me I made friends with the sinless Son of Man who is the well-head of the stream that vitalises our civilisation, and who claims to be the First and the Last and the Living One, who was dead and is alive for evermore, and has the keys of death and the unseen. My experience compels me to own that claim." The changes that had taken place took place under the influence of two factors. There was, first, the extended range of observation that had been opened to sense largely by electricity and the spectrum, and secondly, the guidance that had been given to imagination by the doctrine of evolution. The outer man had acquired instruments of precision, the inner man had been given a clue to guide him through the maze of thought. He then referred in glowing terms to the transformations which he had been made to see. He referred to the doctrine of the ether, to the change in men's ideas regarding the age of the earth, of the appearance of animal life upon it, and of the very constitution of the world. The atom brought from the very verge of thought to guide the chemist in his research had itself been atomised and presented itself now as an object built up of many parts. "It is no longer a solid block but an edifice—a laboratory—into which we can go and see business transacted among the multitude of ions or electrons, where physics is fain to borrow the language of biology for its expression. We seem to ourselves to have come into the borderland where the homogeneous first becomes heterogeneous, where the invisible takes on visibility, where ether clothes itself with matter, and where we are definitely told we may see the mutation of one element into another, so that when we have entered an atom that bore over the entrance the sign of a radium workshop we emerge by a door called helium." He then spoke of how the unit of biology had been transformed. The cell was becoming visible under the microscope when the speaker was born. But the cell was now a speck of bioplasm. In the old nucleus there had been found threads of a life-web resolving into chromosomes which held and could transmit the peculiarities of various forms of life. The plasm dot of a chromosome was again resolved into ids and biophors with their determinants till they might well imagine they had come into a vast cathedral from whose roof there echoed the sound of the voice of one of their brethren of the centuries B.C. who called his treatise on anatomy "A Hymn to the Supreme Being." It was here that they had the most thrilling of all the transformations that had taken place in the thoughts of those who had the gift, the right, and the responsibility to think. Man, "servant and interpreter of nature," soaring among the stars or searching out the secrets of the atom and the cell, had found himself an item in a social cosmos, subject through all its bounds to the reign of law. A composite being capable of communing with the Spirit, who had not at any time, anywhere, among any people, left Himself without a witness, he found that there was nothing alien to him in all the universe. Standing on the summits of creation and summing up in himself the last results of the long processes of evolution he looked to find his ultimate home in One Who was from everlasting to everlasting God. He was the more encouraged to such lofty ideal when he traced his genealogy back, away back to where the foundations of the earth were laid. His mind reflected the mind that fashioned its materials, and somewhere among the ions and the biophors, where he could scarcely tell whether the ion was not already instinct with more than electricity or the biophor held less than life, he saw the narrow fissure between the unseen and the seen, between the not-living and the living, bridged by a kind of virgin-birth, with repetitions of which in some form natural science would make him familiar as he traced the various stages in his own evolution. Professor Simpson then dealt with the individual life. In the germ plasm of some 70,000 primordial ova only four or five were selected to pass through evolutionary processes that would recapitulate at various stages the history of their pre-human genealogy before they came to claim a place in a nation's register. Each of the four, as his evolution still progressed, would find after he had come to himself, and so long as his self-consciousness abides, that the material part of him was subject to incessant change. He was also continually putting off his moral vesture and replacing it with a better-fitting garb. If he reached the Mosaic term of three score years and ten, and if he be wise he would long ere then have pondered how the last fashion of his vestment would be put off. In the years to come they would recall the unusual concurrence of the simultaneous leave-taking of the University by the graduates and their promoter. They would say: "We came away a goodly company through the gateway that leads to the rosy dawn. He passed out, all alone, through the door that leads to the sunset and the evening star. He was an old man, not a great man, he had been a friend of great men, and came out of a great time in the nineteenth century, 'when there was midsea and the mighty things,' and it looked to the men of his generation as if old things had all passed away and a new world begun. And he told us that the great lesson he had learned on his way through life was that 'The world passeth away, and the lust thereof; but he that doeth the will of God abideth for ever.' Farewell." This remarkable address was listened to with the greatest attention and at its conclusion the speaker was accorded loud and prolonged applause. The next incident was the presentation to Professor Simpson of an illuminated address from the students and the new graduates. The presentation was made by Mr. H. J. Norman, president of the Students' Union. The Vice-Chancellor also spoke in feeling terms of Professor Simpson's severance from the University.

University of Aberdeen Quater-centenary.

The recently appointed quater-centenary subcommittee consists of Mr. James Murray, Glenburnie Park, convener of the hospitality committee; Mr. P. J. Anderson, convener of the publications committee; Councillor Alexander Wilson, and Mr. D. R. Thom, secretary of the Senatus. It has visited Glasgow and Edinburgh and had interviews with Sir T. M'Call Anderson, Sir William Turner, Professor Taylor, and Professor D. J. Cunningham (formerly of Trinity College, Dublin). Full information has been obtained regarding the preliminary organisation, publications, and expenses incurred in connexion with the centenary celebrations at Edinburgh in 1884, Dublin in 1892, and Glasgow in 1901.

July 31st.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Royal University of Ireland.

UP to the present year the method adopted at the final M.B. examination of the Royal University of Ireland was as follows. The candidates were first examined in the various subjects (orally, clinically, and by papers) and at the termination the examiners decided, at a meeting, who were to pass and who were to be rejected; they also recommended a certain number for the honour examination and these were again examined by papers, clinically, and orally to decide their relative position on the honour list (of course, there is no clinique in midwifery). Now to this method there were many objections: 1. The candidates were so tired out that it occasionally happened that some of those who were recommended for honour, and might have obtained that distinction, were so wearied with the previous week of the pass examinations that they did not present themselves for the honour contest. 2. The examinations being held in Dublin it involved additional expense to the provincial candidates (board and lodging). 3. It took up much additional time of the examiners, the majority of whom do not live in Dublin. Feeling the weight of these objections many alternative schemes were discussed: (*a*) it was thought by some that one examination alone would be sufficient and that all that was needed was to recommend the candidates who were at the head of the lists and who had done exceptionally well; (*b*) others recommended pass and honour questions to be placed on the same paper, the pass questions being more numerous than the honour; and (*c*) the University of London method was also suggested—that is, to allow a candidate to take honours in special groups (medicine, surgery, or midwifery). The principle finally adopted and put into force for the first time in the spring examinations of this year was a different one Candidates were obliged to state beforehand whether they would go in for the pass or honour course and having decided on one or the other plan they were obliged to keep to this. Pass and honour papers were given out in each group of subjects on the same day, and a candidate having selected an honour paper could not—on finding it too difficult—ask for the pass on the same subject or on any of the other groups. As might have been anticipated, the plan totally failed. 1. Really well-prepared candidates of a timid or self-distrusting nature took the pass papers while others, more optimist in regard to their capabilities, went in for the honour questions. 2. Examiners found it difficult to adjust a proper standard. The duty of an examiner in a pass examination is not so much to throw the candidates into competition with each other but rather to find out whether he can honestly say a particular candidate is fit to pass or not. When it comes to the honour candidates the examiner has first to decide, Have the students come up to the honour standard, and, if so, what is their relative position to one another? This can only be done by the examiners reading together and marking together the answers of each candidate and giving to each on the *vivâ voce* examination identical questions. But suppose some of the candidates are not up to the honour standard then arises the further question, Are they fit to pass? But no provision existed for such a contingency, as the candidates were obliged all through to take the pass or the honour course. The method was found—after the first experience—to be totally unworkable, a point on which all the examiners agreed, and at a meeting of the Senate of the Royal University held on July 27th the following regulations were adopted for the holding of the M.B., B.Ch., B.A.O. degrees examination, to come into force at the October examinations :—

1. That the examinations in medical pathology and surgical pathology be separated, 25 marks being assigned to each.

2. That the pass examination shall be held in all respects in the same manner as heretofore.

3. That the further examination for honours shall be exclusively a written examination and only those candidates can be admitted to it who, upon their answering at the pass examination, are specially recommended for admission by the examiners.

4. That honours shall be awarded not on the examination as a whole, as heretofore, but in the following groups:—(*a*) medicine, theoretical and clinical, including therapeutics, mental diseases, medical jurisprudence, sanitary science, and medical pathology; (*b*) surgery, theoretical, clinical, and operative, including the use of instruments and appliances: ophthalmology and otology, surgical anatomy, surgical pathology; (*c*) midwifery and diseases of women and children.

5. The candidates qualified to present themselves for honours may select one or more of the foregoing groups.

6. The honour papers shall be set on the day following the announcement of the results of the pass examination. They shall consist of (*a*) a paper on medicine and medical pathology; (*b*) a paper on surgery and surgical pathology; (*c*) a paper on midwifery and diseases of women and children, each paper to be of two hours' duration and 100 marks to be assigned to each.

7. The honours in each group shall be awarded taking into account the entire of the marks obtained by the candidate at the pass examination in that group, together with the marks obtained on the honour paper.

8. The exhibitions shall be awarded having regard to all the marks obtained both at the pass and the honour examinations.

Scarcity of Water.

Owing to the warm dry summer many places in the north of Ireland, especially the seaside resorts, are experiencing a drought. In Larne the water-supply is cut off from 4 P.M. until 6 A.M. There is also a scarcity in Bangor, Whitehead, and Portstewart—that is, the supply is intermittent.

Hospital for Diseases of the Skin, Belfast.

At the annual meeting of the supporters of this hospital held on July 29th it was reported that 932 patients had been treated during the past year, of whom 35 were admitted as intern cases. A Finsen lamp of the newest type has been purchased and special thanks were given to Dr. J. C. Rankin (who has charge of the electrical department in the Royal Victoria Hospital) for the help that he gave in the matter of the selection of this lamp. Financially there is a balance to the credit of the hospital of £246 6*s.* 3*d.*

August 1st.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Treatment of Hydatid Cysts of the Liver.

AT a meeting of the Surgical Society held on July 19th M. Guinard said that in his opinion the best method of treating hydatid cysts of the liver was incision preceded by an injection of formol of 1 per cent. strength and followed by extraction of the germinal membrane and suture of the cyst without packing. Since adopting this method he has had uniformly good results. In one of his cases, however, the patient several months after the operation, when he appeared to have completely recovered, returned, having an abundant effusion of bile into the cavity. This effusion was evacuated by puncture and did not recur. This complication would seem to be an argument in favour of packing but these effusions of bile were so rare and could be so easily treated that simple suture without packing must be considered the best treatment.

Removal of the Mammary Glands of Animals in Milk.

At a meeting of the Academy of Sciences held on June 17th M. Porcher stated that removal of the mammary glands of animals in full milk produced marked glycosuria in them during the first few hours after the operation. This glycosuria was at its height in about four or five hours and was accompanied by distinct hyperglykæmia. The glycosuria then declined rapidly and in less than 48 hours after the removal of the glands the urine showed no reducing property. From these researches M. Porcher concluded that the transformation of glucose into lactose (a process necessarily accompanied by the formation of galactose which was found in the excreted lactose) was an intra-mammary function and that lactose could not be formed, as has been alleged, from the union of glucose derived from the blood and galactose derived from the food.

Treatment of Cancer of the Tongue.

At a meeting of the Surgical Society held on July 12th M. Poirier said that in a communication made in 1902 he had recommended for the treatment of cancer of the tongue an operation based on sound logical and anatomical principles. He proposed the systematic and simultaneous removal of the cervical glands and the lingual neoplasm. In 1904 he showed two male patients, one of whom had been operated on 22 months previously and the other 33 months previously, both of them remaining free from any trace of relapse. These operations now dated three or four years back without any appearance of relapse. M. Poirier then considered the question in its histological aspect. Histological data showed that 12 times out of 20 the cervical glands were affected at the onset of cancer of the tongue and their removal in every instance was plainly indicated. As a matter of detail he mentioned that at the beginning of the operation he placed the cannula of a trocar between the cricoid and thyroid cartilages. In conclusion, he expressed regret that many patients suffering from cancer of the tongue sought surgical aid too late, having been buoyed up with false hopes or deceived by the treacherous illusions of radiotherapy or other methods of treatment.

The Use of Movement in the Treatment of Fractures.

Acting on the principle that the bones, like all the parts of the body, require to be freely moved in order that they may attain the full degree of vitality essential for repair, M. Lucas-Championnière, instead of adhering to the classical treatment of fractures by fixation, has replaced it by early mobilisation and massage. During the last 25 years he has treated a very large number of fractures in this way and at a meeting of the Academy of Sciences held on July 10th he described (without entering into specific details) those to which the method was applicable. Among those he enumerated fractures of the upper and lower ends of the humerus; some fractures of the body of this bone; all those of the elbow, including those of the olecranon; many occurring in the two bones of the forearm; fractures of the various bones of the hand and foot and of the scapula; almost all those of the fibula; many bimalleolar fractures; fractures involving the knee and the neck of the femur; and several fractures of the middle of the diaphysis of the long bones of the leg and arm. The principal advantages of massage and early mobilisation were that pain soon disappeared and that the duration of the process of repair was considerably shortened.

Venous Bruit de Souffle at the Level of the Femoral Veins.

At a meeting of the Academy of Medicine held on July 18th M. Molle described some observations which he had made on the occurrence of certain venous blowing murmurs (*bruit de souffle*). He said that at the period of puberty young men might exhibit special symptoms analogous to chlorosis in girls. The condition in question presented, together with numerous indefinite subjective signs, an objective sign of very frequent occurrence, consisting in the presence of blowing murmurs, sometimes of considerable intensity, situated almost exclusively on a level with the femoral veins. In 22 per cent. of the cases observed by him general bad health and overwork (especially the overwork of military service) had induced tuberculosis, which ran a rapid course. He considered that these venous murmurs on a level with the femoral veins ought to be carefully looked for at inspections (*au cours de tournées de révision*) in certain apparently normal individuals. This symptom coexisting with other familiar signs, such as palpitation, breathlessness, indigestion, and asthenia, frequently simulated by malingerers, should be kept in mind with a view to the rejection of persons thus affected.

Vulcanite Tooth Plates.

At a recent meeting of the Société de Médecine Publique M. Eilersten, a dentist in Paris, drew attention to the dangers of vulcanite tooth plates coloured red or pink in imitation of the mucous membrane. He said that wearers of these dentures frequently suffered from buccal inflammation, a sensation of heat or burning, and a spongy state of the gums—conditions which might end in suppuration and inflammation extending as far as the pharynx and larynx, with concomitant salivation and fœtid breath. The symptoms closely resembled those of mercurial stomatitis and dental vulcanite was coloured by a large addition of vermilion, amounting to as much as 30 per cent. of its weight. Vermilion was a sulphide of mercury and was usually considered to be physiologically inert on account of its solubility, but when it was in prolonged contact with the icrobes existing in the mouth the indiarubber was attacked id the vermilion was transformed into soluble salts of ercury which produced mercurial stomatitis and inflammaon of the gums. These views naturally did not meet with ianimous approval at the meeting, and it was pointed out, reply, that persons who did not use artificial teeth were able to the symptoms described quite as often as, if not tener than, the wearers of such teeth. The question was reality one of personal cleanliness and care of the mouth.

July 31st.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Extraordinary Power of Controlling the Muscles.

MEDICAL circles in Vienna have now the opportunity of itnessing some very remarkable examples of muscular tion which a man aged about 30 years is showing in a spital. His power over his muscles is so great that he can rform feats that would usually be deemed incredible. He in contract his abdominal muscles so as to show an idulating movement passing upward and downward; his rynx goes up and down without the aid of the tongue; and e can even cause his pupils either to contract or to dilate, ius showing the influence of the will over so-called inluntary muscular actions. Furthermore, the man, who is joiner by trade, can contract his subclavius muscle and by ius approximating the clavicle to the first rib he compresses is subclavian artery until the radial pulse disappears. By ontracting the diaphragm he is able to displace his heart y four inches. One of his marvellous feats is the "transosition" of the intestines into the space occupied usually y the lungs. By contraction of the abdominal muscles and laxation of the diaphragm the lungs are compressed to about alf of their volume and the intestines are pressed upwards their place; the transference of the viscera is proved by eristaltic movements visible in the thoracic region and by ie x rays. The man trained his muscles under medical ipervision for several years until he attained control over lmost every muscle of his body.

Advertising by Medical Practitioners.

The condition of the profession in several districts is rowing so bad, especially since the laws against unqualified ractice are not enforced to any great extent, that some iedical men have resorted to advertising and two medical ouncils have found it necessary to hold discussions on the ibject. In Salzburg the dental surgeons (fully qualified nd holding the degree of M.D.) who have to meet the ompetition of the unqualified dentists have been permitted y the council to advertise their consulting rooms and hours f attendance in the ordinary newspapers and the example et by them has induced practitioners in a few other cities o do the same, especially as the council has no actual power o prevent them from doing so. In the Vienna Medical ouncil on July 8th there was a very lively debate on the ubject and it is significant of the prevailing opinion that nly a small majority defeated the motion to permit moderate dvertising. Meanwhile the Government continues to turn a eaf ear to the wishes of the profession.

Medical Statistics from Lower Austria.

One of the most pleasing results of improved sanitation is he constant decrease of epidemics and infectious disease in ienna. Thus in 1873 there were 630 cases of small-pox in population of nearly 2,500,000, but since 1895 the number as never exceeded 20 a year, and fell to two in 1902. In 904 there were five cases, all of which were imported, and ne terminated fatally. This is no doubt the result of comulsory vaccination. The mortality from diphtheria has been alling steadily from 33 per cent. in 1883 to less than 12 per ent. in 1902. In 1902 there were 2280 medical practitioners n Vienna—i.e., one for every 735 inhabitants—whilst the flat ountry had only one practitioner for every 2000 inhabitants. nqualified practitioners abounded. These figures have een taken from the "Statistical Year-book for Vienna and ower Austria, 1904," which comprises a period of 20 years 1884-1904). The only increase of infectious disease is in he case of puerperal fever which shows a constant upward endency in spite of all measures to check it; 152 deaths were attributed to it in 1904 as compared with 131 in 1900.

Spirochæta Pallida in the Circulating Blood.

At a recent meeting of the Vienna Clinical Society Dr. Raubitschek showed blood films from a patient who suffered from syphilitic erythema maculo-papulatum over his whole body and also from anal condylomata. Dr. Raubitschek pressed the condylomata between two fingers and the exuding liquid was stained by the method of Giemsa. All films showed the spirochæta pallida (Schaudinn). On the same day a drop of blood was obtained in the usual manner from the fingertip and stained as above mentioned. These preparations gave also clear and definite proof of the presence of the spirochæta. This is the first time that living spirochætæ have been seen in the circulating blood.

A Minute Neuro-fibroma or Suprarenal Adenoma.

At a recent meeting of the Neurological Society Dr. A. Fuchs showed a man who had complained of constant pain under the left costal arch. The pain was increased by pressure or by walking. During the six years of its duration he had noticed that the seat of the pain was at a certain spot from which it radiated. Careful examination revealed the existence of a small hard nodule at this painful point. The nodule, which was of the size of a large pinhead, was excised with a portion of the skin of the abdomen. The pain has since disappeared. Microscopic examination of the nodule, which was supposed to be a simple neuro-fibroma, showed structures which were nearly identical with those of the suprarenal gland. As hitherto it has never been observed that suprarenal formative elements appeared in the ectoderma (skin of the abdomen) this account must be received with the greatest reserve. Several histologists who saw the microscopic preparations concurred with the diagnosis of adenoma suprarenale subcutaneum.

Echinococcus of the Spleen.

Dr. von Schmarda showed at a recent meeting of the Surgical Society a case in which he had performed splenectomy and resection of the left lobe of the liver on account of echinococcus. The patient, who had been suffering for three years from a swelling in the left hypochondrium, was operated upon under local anæsthesia. The bleeding from the liver was controlled by nine deep sutures and a Mikulicz tampon filled the gap made by the splenectomy. The after history was uneventful. There are only 26 cases of splenectomy recorded and this is the first one where operations on the liver and the spleen were simultaneously performed. Echinococcus of the spleen is a very rare disease, only ½ per cent. of the attacks being located in this viscus.

Ontario Medical Association: Annual Meeting.

THE twenty-fifth annual meeting of the Ontario Medical Association was held in Toronto on June 6th, 7th, and 8th, under the presidency of Dr. William Burt of Paris, Ontario, the general secretary being Dr. Charles P. Lusk of Toronto. It was the second largest meeting of the association during its quarter of a century of life. The address in medicine was delivered by Dr. W. B. Pritchard of New York city, the title of the address being "The American Disease: an Interpretation." Dr. A. J. Ochsner, the distinguished Chicago surgeon, delivered the address in surgery, which had for its title "Surgery of the Stomach from the Standpoint of the Clinician." Throughout the meeting the contributions were above the usual level, the discussions being keen, interesting, and profitable. Dr. H. B. Anderson of Toronto communicated a valuable paper on Diseases of the Myocardium from a Clinical Standpoint. Dr. George A. Bingham of Toronto contributed an interesting paper on Exophthalmic Goitre and exhibited some patients upon whom he had recently operated. Dr. H. A. Bruce of Toronto reported 500 operations for appendicitis in the past seven years and advocated the calling in of a surgeon at once by the physician as soon as the latter diagnosed the disease. Dr. Graham Chambers of Toronto read some interesting notes on the cutaneous effects observed in hysterical patients. Dr. W. B. Thistle of Toronto read a paper on the Treatment of Intestinal Lesions in Typhoid Fever, in which he remarked that the last 100 cases of typhoid fever under the care of Dr. W. P. Caven and himself in the Toronto General Hospital had been carried successfully through without a single death, and in all the eliminative treatment, of which Dr. Thistle is an ardent advocate, was employed. Dr. Edward Ryan of Kingston, Ontario, showed several interesting pathological specimens. The others who contributed were as follows:—Dr. J. Biggar (Tilsonburg, Ontario). Broncho-Pneumonia, a Contrast between Rural and Urban Results; Dr. Price Brown (Toronto), the Lymphoid Tonsillar Circle, the Pharyngeal Tonsil; Dr. P. H. Bryce (Ottawa), Types of Immigrants; Dr. George H. Burnham (Toronto), Abnormal Refraction and Eye-Strain; Dr. Caven, Exophthalmic Goitre, exhibition of patients; Dr. F. Fenton (Toronto), Ante- and Post-Partum Examinations; Mr. C. J. C. O Hastings (Toronto), the Duty of the Profession and the State in Regard to the Mental and Physical Care of our Improperly Cared-for Children; Dr. S. M. A. Hay (Toronto), a Critical Review of the Operations for Suspension of the Uterus; Dr. C. A. Hodgetts (Toronto), On the Establishment of a Department of Public Health for the Province of Ontario; Dr. T. K Holmes (Chatham, Ontario), a Summary of 266 Laparotomies, with remarks on the technique adopted; Dr. Henry Howitt (Guelph, Ontario), Remarks on the Surgical Treatment of Chronic Nephritis, with notes of cases; Dr. Goldwin W. Howland (Toronto). Compression Paraplegias following Spinal Caries. and the Results of Surgical Intervention for their Relief; Professor A. B. MacCallum (Toronto), Recent Advances in the Study of the Physiology of Gastric Digestion; Dr. Albert A. Macdonald (Toronto). Ectopic Gestation; Dr. H. T. Machell (Toronto), Modified Milk *v.* Whey Mixtures; Dr. F. W. Marlow (Toronto), Simple Ulceration of the Stomach and Duodenum; Dr. K. C. McIlwraith (Toronto), Clinical Exerience with Labours in Contracted Pelves; Dr. A. McPhedran (Toronto), Evidences resulting from Functional Disturbances of Digestion; Dr. D. Campbell Meyers (Deer Park, Ontario), the Admittance of Certain Forms of Acute Mental Diseases to the Wards of General Hospitals; Dr. James Newell (Watford, Ontario), Report of a Case of Liver Tongue and Report of a Case of Achylia Gastrica; Dr. H. H. Oldright (St. Catherine's, Ontario), a Report of Cases of Electrical Burns and Lesions from Live Wires; Dr. W. Oldright (Toronto), Repair of the Sphincter Ani and Anal Fissure; Dr. Ingersoll Olmsted (Hamilton), Resection of the Splenic Flexure of the Colon—Malignant Disease—with exhibition of patient and specimen; Dr. Charles O'Reilly (Toronto), Remarks on Hospital Management; Dr. C. D. Parfitt (Gravenhurst, Ontario), the Selection of Cases for the Muskoka Free Hospital for Consumptives; Dr. H. C. Parsons (Toronto), Blood Examinations; Dr. J. F. W. Ross (Toronto), Operations for the Immediate Repair of the Genital Lesions of Childbirth; Dr. Rudolf (Toronto), Exophthalmic Goitre, its Medical Treatment; Dr. Paul L. Scott (Toronto), the Clinical Estimation of the Blood Pressure; Dr. C. B. Shuttleworth (Toronto). Exophthalmic Goitre, its Surgical Treatment; Dr. R. W. Bruce-Smith (Toronto), Preludes of Insanity; Dr. T. S. Webster (Toronto), Hysterectomy by Bisecting the Uterus, when indicated; Dr. Hadley Williams (London, Ontario), Tuberculous Adenitis; and Dr D. J. Gibb Wishart (Toronto), the Lymphoid Tonsillar Circle, the Faucial and Lingual Tonsils. It was decided to meet in Toronto in 1906 at the time when it is expected that the British Medical Association will meet there. The following officers were elected for the ensuing year: President, Dr. George A. Bingham, Toronto; treasurer, Dr. F. Fenton, Toronto; secretary, Dr. Charles P. Lusk, Toronto; and assistant secretary, Dr. Samuel Johnston, Toronto.

Ontario Medical Council: Annual Meeting.

The Ontario Medical Council met in Toronto in annual session during the week ending July 8th, when the following officers were elected for the ensuing year: President, Dr. Albert A. Macdonald, Toronto; vice-president, Dr. W. H. Moorhouse, London; registrar, Hon. Dr. R. A Pyne, Toronto; treasurer, Dr. H. Wilberforce Aikens, Toronto; and auditor, Dr. J. C. Patton, Toronto. During the progress of the meeting several interesting and important matters concerning the profession in the province of Ontario were taken up and attended to. On the report of the official prosecutor being presented action was taken on that part of it which referred to the prosecution of Christian Scientists and it was decided to approach the legislature of the province to seek an amendment to the Medical Act which would empower the council to deal with these people. A special committee was also appointed to wait on the legislature to solicit a substantial grant toward the erection of sanatoriums for consumptives in different sections of the province. Still another matter of importance dealt with was the appointment of a special committee to wait upon the Government to request the establishment of a department of public health for the province. The official prosecutor reported that during the past official year 52 cases had been dealt with. Of this number convictions had been secured in 24 cases, nine had left the country, 11 were dismissed, and six were not proceeded with, which goes to show that quacks do not thrive to any extraordinary extent in the province of Ontario.

July 25th.

NEW ZEALAND.

(FROM OUR OWN CORRESPONDENT.)

Honorary Degree conferred on Dr. D. Macgregor.

THE honour bestowed upon our Inspector-General of Hospitals, Dr. D. Macgregor, by the University of Aberdeen is keenly recognised by the profession here. Previously to being asked to rule the asylums and hospitals Dr. Macgregor was lecturer on moral philosophy at the medical school at Dunedin. There are few more fearless or eloquent servants of this or any other State than the newly elected LL.D.

The Prevention of Tuberculosis.

The movement for providing annexes for the reception and treatment of indigent consumptives is spreading. Christchurch has made a beginning and public meetings have been called in Invercargill. The paper read by the Minister of Health (Sir J. G. Ward) at the last meeting of the Intercolonial Association for the Advancement of Science held at Dunedin has been productive of great good.—Lady Plunket (wife of His Excellency the Governor) opened the Women's Colony of Nurse Maud's Camp at Christchurch last week. The report stated that the percentage of "cures" obtained at this open-air camp for consumptives was higher than that of many of the sanatoriums on the continent of Europe. Nurse Maud is deserving of high praise for her work on behalf of the indigent consumptive.

The Parliamentary Session.

Parliament will meet on June 27th and it is reported that among the measures to be introduced will be a Food and Drugs Bill, a Medical Registration Act, a Hospitals Act, and some amendments to the Public Health Act. There is urgent need for some alterations in the law regulating medical practice At present, although a New Zealand student is required to follow out a five years' course of study, anyone with a three years' medical education at almost any school in any country can be admitted to our register.

Conference on Dentistry.

The dentists held a most successful conference this month in Wellington. There were upwards of 100 in attendance at some of the meetings. Among the papers of more general interest and value was one by Mr. Thompson of Christchurch on the Care of the Teeth of Children. He advocated among other measures the regular examination by State officers of the teeth of the children attending the State schools. As a result of his advocacy a deputation waited upon Sir J. G. Ward, Minister of Health, who gave them a most cordial reception. He stated that he realised the value of the suggestions made and promised to lay the question of State examination before the Cabinet. The President (Mr. E. Rawson) gave a most interesting account of dentistry in the early days of the colony.

Treatment of Moveable Kidney.

At the meeting of the Wellington branch of the British Medical Association last week Dr. W. E. Collins of Wellington read a paper recounting the results of his operation for moveable kidney. The main features in the operation are the stripping of the capsule, more especially at the upper pole; the fixation of the kidney in its normal position while the patient is in the Trendelenburg position; the passing of the ligatures for the anchorage through the lower end of the kidney; and the keeping of the patient in such a position after the operation that there will be the least possible disturbance to the organ caused by coughing, vomiting, &c. The kidney by this method of operation is fixed in its normal position with very little injury to the kidney itself or disturbance of the surrounding parts.

Various Items of News.

His Excellency the Governor presided at a meeting held in Dunedin last week having for its object the raising of funds for additions to the hospital of the "Edinburgh of the Antipodes."—The recently appointed professor of physiology to the medical school took up his duties at the beginning of the month and was welcomed by his fellow teachers. Hitherto Professor J. H Scott, who has done so much for the school, has held both the chairs of anatomy and physiology.—At the Intercolonial Medical Congress to be held in September at Adelaide, New Zealand will be represented by Dr. J. M. Mason, the chief health officer of the colony.

The New Zealand International Exhibition.

The Government of New Zealand has decided to hold an international exhibition at Canterbury in that colony from November, 1906, to the early part of April, 1907. One of the principal objects of the exhibition is to demonstrate the resources and possibilities of the colony as a food-producing ountry and a tourist resort and to bring under the notice of ndustrial nations the great field for enterprise which it ffers for the use of manufactured articles. Applications for pace may be lodged with the Agent-General for New Zealand, Westminster Chambers, 13 Victoria-street, London, or with the secretary of the exhibition, Christchurch, New Zealand.

Wellington, June 12th.

Obituary.

GIOVANNI ANGELO CALCINARDI.

THE great and growing Italian colony in South America has lost one of its most prominent representatives in Dr. G. A. Calcinardi, whose death is just reported from Pando in the Uruguayan Republic. Born 70 years ago at Desenzano in the province of Brescia, he studied medicine at Padua, but, like nearly all his generously inspired fellow students, he was swept into the revolutionary vortex and, less fortunate than others, was arrested by the Austrian authorities, tried, and condemned to death. Having, however, escaped from prison he took refuge in Piedmont and completed his studies at Turin and in Paris, taking in due course his degree as doctor. By this time (1860) the movement towards Italian unity and independence was in full career and young Calcinardi was among the volunteers who joined Garibaldi in the descent on the Two Sicilies. In that brilliant raid, at once Quixotic and successful, he was repeatedly under fire but outlived all its dangers to resume professional work in the regular army where he became "capitano medico." Two years afterwards, when Garibaldi raised the cry of "Roma o Morte," young Calcinardi succumbed to the spell of his old leader, threw up his appointment in the army, shared in the disastrous day of Aspromonte, and was again condemned to death, on this occasion by the Italian Government. The sentence, however, was not carried out and in 1867 Garibaldi found his enthusiastic volunteer for the third time by his side in the next raid upon Rome, which closed (once more in disaster) on the field of Mentana. Excluded from his former career on the army medical staff, while pardoned by the Government, he repaired to South America, where in general practice he rapidly realised a fortune which enabled him to gratify his longing to see Italy once more. Settling in Milan he again succeeded in winning a large *clientèle*, his earnings from which he devoted to charity, public and private, on a munificent scale. Interested in the problem of emigration and all that it means for the poor Italian emigrant he took service on board one of the transatlantic liners and followed up his inquiries on American soil. His mission completed he resumed practice again at Milan, whence he moved to Carpesina and then to his native Desenzano. Here he was assisted by his son, by this time a graduate in medicine, whom, for the furtherance of his professional career, he accompanied to Uruguay, where they both practised in concert. Of late years, however, the fatigues of his chequered and self-sacrificing life had begun to tell upon him, exceptionally robust as he was in constitution and character; so, after struggling awhile against daily increasing infirmity, he succumbed on May 27th, leaving behind him in his native Italy and in the Italian colony of South America the memory of a nobly inspired enthusiast in the cause of his country and of his fellow men.

GLOUCESTER HOSPITAL FOR CHILDREN.—The Bishop of Gloucester formally opened on July 26th a new dispensary which has been added to the Gloucester Children's Hospital as a memorial to the late Mr. Gambier Parry.

Medical News.

UNIVERSITY OF OXFORD.—At examinations held recently the following were successful in the subjects indicated:—

FINAL HONOUR SCHOOL OF PHYSIOLOGY.—CLASS LIST.

First Class.—O. L. V. Simpkinson, Corpus Christi, and D. Trimmer, Christ Church.

Second Class.—C. N. Binney, Corpus Christi; M. Davidson, Trinity; M. W. Flack, Keble; G. R. Hughes, Exeter; and P. T. Spencer Phillips, New College.

Third Class. P. H. C. Fowell, St. John's; J. F. Hornsey, Wadham; S. F. Moore, Trinity; and S. S. Strahan, Keble.

Fourth Class.—R. F. B. Bowes, Queen's; G. A. Hope, New College; W. D. Kennedy, University; A. J. W. Milroy, Christ Church; A. H. Savage, New College; and C. F. M. West, Christ Church.

Passed.—J. R. Kay-Mouat, Hertford.

PRELIMINARY EXAMINATION.—PASS LISTS.

Mechanics and Physics.—H. C. Bazett, Wadham; A. M. Carr Saunders, Magdalen; N. G. Chavasse, Trinity; T. Clear, Balliol; D. Edwardes-Ker, Brasenose; H. Hinds, Queen's; G. A. Hutchinson and G. L. M. Inkster, Balliol; E. G. Laws, Non-collegiate; W. O. Little, New College: H. H. W. Lydall, Merton; D. P. McDonald, Oriel; L. N. Morrison, St. John's; W. J. Oliver, Oriel; W. G. Pinching, St. John's; J. P. Purnell Edwards, Christ Church; J. Russell, Balliol; C. J. G. Taylor, University; W. H. Thornton, Trinity; J. T. Wills, Non-collegiate; M. Wilson, Hunter-Blair's Hall; C. C. Wilson, Queen's; R. C. Wingfield, Trinity; and C. F. Younger, New College.

Physics.—T. Bentham, Queen's; G. C. Boyd and M. de G. Boyd, Lincoln; G. W. Carte, New College; A. R. Chavasse and A. W. Donaldson, Hertford; A. M. Lupton, Trinity; J. W. Mason, Jesus; G. H. Udall, Queen's; G. H. Varley, St. John's; and W. E. Waller, University.

Chemistry.—E. Bate, St. John's; H. C. Bazett, Wadham; W. F. G. Blackler, Trinity; G. C. Boyd and M. de G. Boyd, Lincoln; A. J. B. Carrington, University; A. R. Chavasse, Hertford; N. G. Chavasse, Trinity; T. Clear, Balliol; P. G. Doyne, Trinity; D. R. Edwardes-Ker, Brasenose; P. R. Fairclough, St. John's; C. L. Garton, Magdalen; T. H. J. Gillam, Hertford; J. K. Hepburn and G. B. Holmes, Queen's; G. A. Hutchinson and G. L. Inkster, Balliol; E. G. Laws, Non-collegiate; J. M. Mason, Jesus; H. G. Morris, University; W. J. Oliver, Oriel; A. S. Roe, Balliol; D. Roy, Wadham; E. P. Sells, Christ Church; G. Stanger, Lincoln; C. J. G. Taylor, University College; G. E. Thornton, Oriel; G. H. Udall; Queen's; M. Wilson, Hunter-Blair's Hall; C. C. Wilson, Worcester; R. C. Wingfield, Trinity; J. H. Worthington, Wadham; and C. F. Younger, New College.

Zoology.—T. B. Batchelor, University; H. C. Bazett, Wadham; P. N. Cave, University; G. H. Cross, Balliol; A. W. Donaldson, Hertford; C. C. Gaunt, St. John's; and H. G. Morris, University.

Botany.—P. P. Andrews, University; H. C. Bazett, Wadham; J. L. Birley, University; W. F. G. Blackler, Trinity; A. M. Carr-Saunders, Magdalen; P. N. Cave, University; H. E. Clarke, Jesus; G. H. Cross, Balliol; G. B. Downs, Magdalen; C. C. Gaunt, St. John's; H. O. S. Gibson, New College; G. D. Knox, Balliol; E. L. Pearce-Gould, Christ Church; A. S. Roe, Balliol; H. W. Scott Wilson, Queen's; G. E. Thornton, Oriel; W. W. Wagstaffe, New College; R. O. Ward, Queen's; R. C. Wingfield, Trinity; and T. S. Wright, Brasenose.

UNIVERSITY OF EDINBURGH.—The following degrees and certificates were conferred on July 28th:—

Doctor of Medicine.—Francis John Harvey Bateman, England, M.B., C.M., 1893; Charles Mackie Begg, New Zealand, M.B., Ch.B., 1903; ‡Raphael Aaron Belilios, India, M.B., Ch.B., 1901; John Francis Gibbs Bent, England, M.B., C.M., 1893; Harry Edward Bower, England, M.B., C.M., 1887; George Edward Bowker, England, M.B., C.M., 1891; Arthur John Brock, Scotland, M.B., Ch.B., 1901; ‡Robert Dods Brown, Scotland, M.B., Ch.B., 1902; †James Burnet (M.A.), Scotland, M.B., Ch.B., 1898; Osmund Harry Chapman, England, M.B., C.M., 1894; ‡Harry Lovett Cumming, Scotland, M.B., Ch.B., 1902; †James Davidson, Scotland, M.B., Ch.B., 1903; †George Augustus Davies (B.A.), England, M.B., Ch.B., 1903; †Frank Inglis Dawson, Scotland, M.B., Ch.B., 1902; *William Elliot Carnegie Dickson (B.Sc.), Scotland, M.B., Ch.B. ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the sittings of the Scottish Conjoint Board held in Glasgow the following candidates passed the respective examinations —

First Examination (five years' course)—Robert Henry Jones, Pen y-groes, Dennis Cogan, Cork, Thomas Sholto Douglas, Glasgow, Jehangir Cawasji Balsara, Portobello, William George Hugh Brooks, Portobello, Robert Stobo Watt, Glasgow, Phiroza Malabari, Glasgow, and Daniel Murphy, Edinburgh.

Second Examination (five years' course).—Matthew H Fleming, Glasgow, Walter Biddell Glasgow; George Lindsay Irwin, Glasgow, Alexander Paul Dias, Portobello, and Abraham David Woolf, London.

Second Examination (four years' course).—George Munro Macleod, Glasgow.

Third Examination.—Hugh Graham Anderson, Newlands, Glasgow, James Logan, Maryhill, John Dawson, Queenstown, Ireland, Andrew Baxter, London, Alexander Dick, Belfast, John Arthur Smith, Kelvinside, and Kenneth James Logan Bannerman, Partick.

Final Examination (and admitted Licentiate of the Three Cooperating Authorities).—William Noble Walker, Greenock, William Wallace Dempster, Belfast; William Patrick Timmon, Navan, Meath, Ireland, Whitfield de Witt Henty, Edinburgh, Joseph Owens, Glasgow, John [illegible] ck on Shannon, Lorris Elijah Bor[illegible] olas Alexander, Dublin Herbert [illegible] awsajee Balsara, Portobello Juliu[illegible]. John Priestley Newton, Glasgow, [illegible] ech, Edinburgh, James Taylor, Dunalister, Castlehead, Paisley (with honours), Alexander Dick, Belfast, and John Gilbert Heathcote, Ardwick, Manchester.

CLERICAL, MEDICAL, AND GENERAL LIFE ASSURANCE SOCIETY.—Mr. Arthur Digby Besant, B.A., F.I.A., has been appointed secretary of this society and Mr. W. J. H. Whittall remains principal officer with the title of actuary.

NOISY DOGS.—At the Exeter police-court on July 25th a butcher was fined £1 and costs, under the new by-law, for keeping noisy dogs to the annoyance of his neighbours.

DONATIONS AND BEQUESTS.—Mr. J. Storrs Fry has given £1000 towards the cost of the isolation wards of the Bristol General Hospital, which are shortly to be erected at an estimated cost of about £5000.—The Royal Dental Hospital of London, Leicester-square, has received a donation of £100 from the Worshipful Company of Grocers.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Bills Withdrawn.

Two Bills have been withdrawn this week of which a word may be said. One was to prohibit persons who are not by examination and registration legally qualified to practise medicine and surgery from carrying on business as medical practitioners by means of companies formed under the Joint Stock Companies Acts. The other was to prohibit the carrying on of dental practice by unqualified persons by means of limited companies. Both were presented by Sir JOHN BATTY TUKE and supported by Sir JOHN BRUNNER, Mr. JAMES CAMPBELL, Mr. CATHCART WASON, Sir MICHAEL FOSTER, and Sir WALTER FOSTER. To have had any chance of success they should have been introduced in the early days of the session, they were not brought forward till a few weeks ago. The only advantage obtained, and, of course, it is one that is not to be ignored, is that the Bills have been printed and circulated.

The Registration of Nurses.

The Select Committee of the House of Commons appointed to consider the question of providing for the registration of nurses has shown expedition in agreeing upon its report. Elsewhere the text is given. It is probable that an effort will be made early in next session to secure Government action upon the lines of the report.

HOUSE OF COMMONS.

WEDNESDAY, JULY 26TH.

Midwifery Orders for Poor Women.

Sir WALTER FOSTER asked the President of the Local Government Board whether he had considered the difficulty which poor women might experience in getting assistance in their confinements in consequence of unregistered midwives being afraid to attend, as in the Smallburgh union, and whether he could take steps to point out to boards of guardians the duty of the relieving officer to grant midwifery orders to women destitute of the means of procuring medical attend- [illegible] t present I am not aware [illegible] cers generally do not realise [illegible] some inquiry on the subject [illegible] union.

THURSDAY, JULY 27TH.

The List of Poisons.

Sir JOHN LENG asked the Home Secretary whether, in view of the fact that the Council of the Pharmaceutical Society of Great Britain recently resolved that each of ten different articles should be declared a poison within the meaning of the Pharmacy Act, 1868, and that, in conformity with the report of the Departmental Committee on Poisons and the views of coroners and medical men these ten articles included acetanilide, soluble salts of oxalic acid, and sulphonal, he would explain why these three articles were excluded from the list of poisons approved by the Lords of the Privy Council and advertised accordingly in the *London Gazette* of July 18th.—Mr AKERS DOUGLAS answered: I have communicated on this matter with the Lord President of the Council, who informs me that the Lords of the Privy Council, after consideration of the substances covered by the terms of the resolution of the Pharmaceutical Society, and after taking expert advice upon the subject, decided, in the exercise of the discretion with which they are invested by Section 2 of the Pharmacy Act, 1868, to exclude from their approved list the three substances named in the question.

Roman Catholic Nurses in Southern Nigeria.

Mr SLOAN asked the Secretary of State for the Colonies whether the High Commissioner of Southern Nigeria acted on his own initiative in inviting at the beginning of the present year a sisterhood of French nuns to Calabar to take charge of the native Government hospital, where the inmates were non Catholic; for what period these nuns had been engaged, and whether it was intended to retain their services in preference to nurses who were not connected with religious orders.—Mr. LYTTELTON answered: The proposal that two Roman Catholic sisters should be employed as nurses in the native hospital at Calabar (which is a separate institution from the European hospital) was originally made to the Protectorate Government by the head of the Roman Catholic Mission at Calabar in September, 1903. There had previously been no women nurses at the native hospital and, as the proposal received the support of the principal medical officer and of the Acting High Commissioner, it was accepted on terms which were referred to, and approved by, me. It was stated in the terms of agreement that no undertaking could be given that the sisters would be employed for any stated period but if the system is found to work well I see no reason, on the information before me, why it should be changed.

Mosquito Nets and Fever.

Mr. CATHCART WASON asked the Secretary of State for the Colonies whether he was aware that railway employés in West Africa were constantly stricken with fever through old and defective mosquito nets and whether he would give instructions that the nets in use should be constantly reported on and that any employé refusing or neglecting to use the same should be liable to instant dismissal.—Mr LYTTELTON replied: I am not in a position either to corroborate or to deny what the honourable Member alleges as to the causing of fevers. I cannot, however, undertake to direct the holding of inquisitions as to whether railway employés use their nets or not. These employés are adult skilled workmen and must be regarded as having some personal intelligence and responsibility.

THE REGISTRATION OF NURSES: REPORT OF THE SELECT COMMITTEE.

The Select Committee of the House of Commons appointed to consider the expediency of providing for the registration of nurses has presented the following report to Parliament:—

The committee has examined 34 witnesses, among whom are included members of the medical profession, matrons of hospitals, superintendents of nursing institutions, nurses whose experience has been gained abroad as well as nurses who carry on their occupation in this country, a representative of the male nurses, representatives of various institutions and public bodies, including the Civil Service, besides ladies and gentlemen who are not professionally employed but who have given much time and work to the management of hospitals and asylums and to the study of nursing questions both in the centres of population and in the rural districts. Amidst many divergent views met with in this evidence there is a general opinion in favour of some change in the conditions under which nursing is carried on. The committee has observed this tendency in the evidence of the medical profession and in that of the nurses themselves. The evidence shows that a considerable improvement has taken place of late, both in the class of persons who undertake nursing and in the conditions under which they obtain their training and carry on their occupation. It has been asserted in some quarters that registration is rendered requisite by reason of the amount of illegality, immorality, and scandal which at present continues undiscovered and unchecked. It is contended that registration would be an efficient instrument against these scandals and would safeguard the public. In the judgment of the committee, while registration might prove a means towards checking some abuses no evidence which has been brought forward substantiates a general charge of moral delinquency. On the other hand, there is a general concurrence of opinion that in the interests of the nurses and of the public further improvement is both desirable and practicable and the committee considers that the desire for coordination of the various training schools, although not universal, is widespread. Upon the question of what changes in the conditions of nursing are desirable strong opinions are held and vigorous expression has been given to them. In these circumstances unanimity could not be looked for. The principal suggestions laid before the committee are:—(*a*) Registration of individual nurses, (*b*) registration of training schools for nurses, and (*c*) licensing of nursing homes, institutions, and societies which supply or employ nurses. The committee is agreed that it is desirable that a register of nurses should be kept by a central body appointed by the State and that, while it is not desirable to prohibit unregistered persons from nursing for gain, no person should be entitled to assume the designation of "registered nurse" whose name is not upon the register. It recommends that this central body should be set up by Act of Parliament and that its constitution should be defined in the Act, as was done in the case of the Central Midwives Board. The central body should consist of matrons, nurses, and representatives of the medical profession, of training schools for nurses, and of the public. The committee considers it desirable that the number of representatives should be kept within reasonable limits, it suggests 11 as a convenient number and recommends that it should never exceed 15. The committee recommends that the central body should admit to the register of nurses such nurses as have had a training at a recognised training school for nurses for a period to be determined by such body, and have satisfied their training school, whose certificate they must hold, stating that they are equipped with the knowledge and experience requisite for nursing and that they are of good character. It also recommends that the central body should decide what constitutes a recognised training school for nurses, taking into consideration the number of beds, the accommodation for probationers, the facilities afforded for learning, and the general standard and conduct of the examination, for this purpose the central body should have the power of inspection The committee further recommends that the examination be held at, and by, the training school For the purpose of defraying the expenses of the central body a small registration fee should be charged The committee considers that this fee should not exceed one guinea The committee has heard a large amount of evidence on the subject of the necessary period of training at a school The great bulk of this evidence points to three years as the requisite period of training It is impressed with the advisability of such a period but it recognises that a stereotyped rule might operate unfortunately It therefore recommends that the minimum period should not be fixed by Act of Parliament but should be left to the discretion of the central body There should be an annual publication of the register of nurses For this purpose the central body should make provision for striking off the register the names of those nurses who have died or who have ceased nursing, and also of those nurses who, in the opinion of the central body, have been guilty of serious misconduct in the discharge of their duty or of moral delinquency With regard to existing nurses the committee is of opinion that those who can produce evidence satisfactory to the central body both as regards efficiency and character should be placed upon the register on payment of the registration fee The committee is of opinion that it should be the duty of the central body at a date not later than four years after the passing of any Act for the registration of nurses to submit a report to the Privy Council on the advisability of instituting a separate register of nurses whose training is of a lower standard than that laid down for "registered nurses" The claims for registration of mental or asylum nurses have been laid before the committee It is of opinion that a separate register of "registered asylum nurses should be kept by the central body to which should be admitted the names of nurses who have served for not less than three years (in not more than two asylums), and have received the certificate of the Medico Psychological Association, and can produce satisfactory certificates of good character An analogous but separate question has come before the committee—namely, the treatment of nursing homes [illegible] homes are deemed to include all homes and [illegible] where patients are taken in for treatment [illegible] meant those societies or bodies which supply nurses to the public. The evidence laid before the committee has led it to consider the licensing of such homes and institutions to be highly desirable The licence should be issued by the county or county borough authority in whose area the home or institution is situated, and no such home or institution should receive the licence unless it is conducted in conformity with requirements to be laid down by that authority The county or county borough authority should be empowered to draft regulations to be approved by the Local Government Board and to appoint inspectors who should have the right of entry and inspection It should be a condition of such licence that when a nurse employed in a nursing home or sent out by a nursing institution is not a "registered nurse" the fact shall be definitely stated.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub Editor, not later than 9 o clock on the Thursday morning of each week, such information for gratuitous publication*

CAMERON, WILLIAM JOHNSTONE, M B, Ch B Edin, has been appointed Public Vaccinator to Mildura, North Western District of Victoria, Australia

CLAY, ROBERT HOGARTH, M D, M R C P Edin, has been appointed Honorary Medical Adviser to the Devon and Cornwall Home for Consumption, Didsworthy

COLLIER, H W, M B, B S, has been appointed Clinical Assistant to the Chelsea Hospital for Women

CORBETT, W E MANDERSON, L R C P & S Irel, has been appointed Honorary Medical Adviser to the Devon and Cornwall Home for Consumption Didsworthy

GRAY, COLIN, M B, Ch B Melb, has been appointed *pro tem* Public Vaccinator for the Midland District Victoria, Australia

HOPE, WILLIAM WAUGH, M B, Ch B Melb, has been appointed *pro tem* Acting Officer of Health for the Shire of Colac, Victoria, Australia

INGHAM, JAMES HERBERT IVEY M B, Ch B Melb, has been appointed Public Vaccinator for the North Western District and to be Acting Health Officer for the Shire of Dimboola, Victoria, Australia

JACKSON, GEORGE F R C S Eng, L R C P Lond, has been appointed Honorary Medical Adviser to the Devon and Cornwall Home for Consumption, Didsworthy

LINDSEY, COLIN DUNROD, M A, M D, B C, D P H Cantab, has been appointed Honorary Medical Adviser to the Devon and Cornwall Home for Consumption, Didsworthy

MAURICE, W B, M R C S, L R C P, has been appointed Clinical Assistant to the Chelsea Hospital for Women

ROBINSON, W, L R C P, L R C S, has been appointed Clinical Assistant to the Chelsea Hospital for Women

SPRING, WILLIAM AMBROSE, M B, Ch B Melb, has been appointed *pro tem* Acting Officer of Health for the Shire of *Ballarat*, Victoria, Australia

TAYLOR MARK RONALD, L R C P Lond, M R C S, has been appointed Medical Officer of Health of Helston, Cornwall

TOYE, EDWIN JOSIAH, M D, B S Lond, F R C S Eng, L R C P Lond, has been appointed Medical Officer of Health for the Northam (Devon) Urban District Council

TRIADO, A J. J, M B, Ch B Vict, has been appointed District Medical Officer of Lawlers, West Australia

WEBBER, H WOOLMINGTON, M D, M S Lond, F R C S Edin has been appointed Honorary Medical Adviser to the Devon and Cornwall Home for Consumption, Didsworthy

WOOLLCOMBE, WALTER LEY, F R C S Edin, M R C S, L R C P Lond, has been appointed Honorary Medical Adviser to the Devon and [illegible] mption, Didsworthy

[illegible] M B M S Edin, has been appointed [illegible] geon to the Huddersfield Infirmary

[illegible] Ch, D P H Vict, has been appointed Certifying Surgeon under the Factory and Workshop Act for the Prescot District of the county of Lancaster

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index)

ALDERSHOT URBAN DISTRICT COUNCIL —Medical Officer of Health and Superintendent of the Isolation Hospital Salary £300 per annum (being £275 as Medical Officer of Health and £25 as Medical Superintendent of the Isolation Hospital, &c)

BIRKENHEAD BOROUGH HOSPITAL.—Senior and Junior Resident House Surgeons Salaries £100 and £80 respectively, with fees

BOURNEMOUTH, ROYAL VICTORIA HOSPITAL.—House Surgeon. Salary £100 per annum, with board and lodging

BOURNEMOUTH, ROYAL NATIONAL SANATORIUM —Resident Medical Officer Salary £10 per month, with board residence and washing

BURY INFIRMARY —Senior House Surgeon Salary £110 with board, residence, &c.

DOUGLAS, ISLE OF MAN, NOBLES ISLE OF MAN HOSPITAL AND DISPENSARY —Resident House Surgeon, unmarried Salary £90 a year, with board and washing

EXETER CITY ASYLUM —Assistant Medical Officer Salary £150 a year with board, lodging, and washing

GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—House Surgeon. Salary £100, with board, residence, and laundry Also Assistant House Surgeon Salary £50, with board, residence, and laundry

IRELAND, MEDICAL SCHOOL, ROYAL COLLEGE OF SURGEONS.—Senior Demonstrator of Anatomy Stipend £100 per annum

KENSINGTON WORKHOUSE AND INFIRMARY —Second Assistant Resident Medical Officer Salary £80 per annum, with apartments, board, and washing

[illegible] ENTIVE MEDICINE.—Assistant Bacteriologist.

[illegible] COLLEGE OF MEDICINE (UNIVERSITY OF DURHAM) —Lecturer in Medical Jurisprudence

ROXBURGH DISTRICT ASYLUM, Melrose, N B —Assistant Medical Officer Salary £140 per annum, with board, rooms &c

SALOP INFIRMARY, Shrewsbury —House Surgeon Salary £100 per annum, with board, washing, and residence

SHEFFIELD ROYAL INFIRMARY —Junior Assistant House Surgeon. Salary £65 per annum, with board lodging, and washing Also Junior House Physician Salary £60 per annum, with board, lodging, and washing

SOUTHAMPTON, ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—House Physician Salary £100 per annum, with rooms, board and washing

STRAITS SETTLEMENTS, MUNICIPALITY OF THE TOWN OF SINGAPORE.—Assistant Municipal Health Officer. Salary £400 per annum, rising to £450

THE Chief Inspector of Factories, Home Office, S W, gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Westbury, in the county of Salop, and at Gargrave, in the county of York

Births, Marriages, and Deaths.

BIRTHS.

BABTIE —On July 31st, at Carlisle mansions, S W, the wife of Lieutenant Colonel W Babtie, V C, C M G, Royal Army Medical Corps, of a daughter

MICHÔD —On July 26th, at Roma, Queensland, the wife of F A Hope Michod, M B Lond, M R C S, L.R C P, of a son

MARRIAGE.

BATESON—GLADSTONE —On July 26th, at Childwall Parish Church, Surgeon Major John Francis Bateson, Coldstream Guards to Helen Steuart, daughter of Robert Gladstone, of Woolton Vale, near Liverpool

DEATHS.

BLAKE —On July 31st, at Seymour street, W, Edward Thomas Blake, M D, M R C S Eng, aged 63 years

FRAZER On July 26th, at Elmhurst, Bournemouth, William Frazer, M D, aged 54 years

GRANT —At 26, Dundas street, Edinburgh, on July 27th, Louisa Elizabeth, widow of the late James Dundas Grant, Advocate, and mother of J Dundas Grant, Leonard Grant, C Graham Grant, and Hope Grant, London, in her eighty first year

MORRIS —On July 30th, at Hamilton House, Leamington, Joseph Morris, M R C S L R C P, L S A, aged 70 years

OAKESHOTT —On July 27th, of pneumonia, Walter Field Oakeshott, M.D, M R C S, L R C P, of Lydenburg, Transvaal

N.B.—A fee of 5s is charged for the insertion Notices of Births, Marriages, and Deaths.

afforded for learning and the general standard and conduct of the examination, for this purpose the central body should have the power of inspection The committee further recommends that the examination be held at, and by, the training school For the purpose of defraying the expenses of the central body a small registration fee should be charged The committee considers that this fee should not exceed one guinea The committee has heard a large amount of evidence on the subject of the necessary period of training at a school The great bulk of this evidence points to three years as the requisite period of training It is impressed with the advisability of such a period but it recognises that a stereotyped rule might operate unfortunately It therefore recommends that the minimum period should not be fixed by Act of Parliament but should be left to the discretion of the central body. There should be an annual publication of the register of nurses For this purpose the central body should make provision for striking off the register the names of those nurses who have died or who have ceased nursing, and also of those nurses who, in the opinion of the central body, have been guilty of serious misconduct in the discharge of their duty or of moral delinquency With regard to existing nurses the committee is of opinion that those who can produce evidence satisfactory to the central body both as regards efficiency and character should be placed upon the register on payment of the registration fee The committee is of opinion that it should be the duty of the central body at a date not later than four years after the passing of any Act for the registration of nurses to submit a report to the Privy Council on the advisability of instituting a separate register of nurses whose training is of a lower standard than that laid down for "registered nurses The claims for registration of mental or asylum nurses have been laid before the committee It is of opinion that a separate register of "registered asylum nurses should be kept by the central body to which should be admitted the names of nurses who have served for not less than three years (in not more than two asylums), and have received the certificate of the Medico Psychological Association, and can produce satisfactory certificates of good character An analogous but separate question has come before the committee—namely, the treatment of nursing homes . . . homes are deemed to include all homes and where patients are taken in for treatment meant those societies or bodies which supply nurses to the public. The evidence laid before the committee has led it to consider the licensing of such homes and institutions to be highly desirable The licence should be issued by the county or county borough authority in whose area the home or institution is situated, and no such home or institution should receive the licence unless it is conducted in conformity with requirements to be laid down by that authority The county or county borough authority should be empowered to draft regulations to be approved by the Local Government Board and to appoint inspectors who should have the right of entry and inspection It should be a condition of such licence that when a nurse employed in a nursing home or sent out by a nursing institution is not a "registered nurse' the fact shall be definitely stated.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (7th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.).

ESDAY (8th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.).

EDNESDAY (9th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.) Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M., National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopædic (3 P.M.).

HURSDAY (10th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.).

RIDAY (11th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.).

ATURDAY (12th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

THURSDAY (10th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith road, W.).—4 P.M. Mr. Armour: Surgical Cases.

FRIDAY (11th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W).—5 P.M. Mr. Baldwin: Treatment of Injuries of Tendons, Muscles, and Nerves.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1905, which was completed with the issue of June 24th, and the Title-page to the Volume, were given in THE LANCET of July 1st.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1905 are now ready. Bound in cloth, gilt lettered, price 18*s*., carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s*., by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are :—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTICE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

During the week marked copies of the following newspapers have been received:—*Exeter Flying Post, British Food Journal, British Australasian, Birmingham Post, Halifax Guardian, Whitehaven News, Dewsbury District News, Morning Post, Western Times (Exeter), Manchester Courier, Dublin Independent, Cardiff News, Daily News, Times, Truro Gazette, Durham Chronicle, St. Austell Star, Bangor Observer, Morning Leader, Dublin Express, Bolton Chronicle, Middlesbrough Gazette, Leeds and Yorkshire Post, Manchester Evening News, Limerick Chronicle, Yorkshire Herald, Crusader, Notts Guardian, Darlington Star, Leicester Mercury, Norwich Eastern Daily Press, &c.*

"DR. WALFORD BODIE" AND HIS TITLES.

The following amusing letter has appeared recently in the Aberdeen *Evening Express* :—

> Sir,—I have just received a copy of your issue of the 11th inst. containing a report *re* the above. As your correspondent has not given you all the facts and as I am anxious that my fellow-townsmen should know the full particulars of the case I should feel obliged if you would grant me space in your valuable paper to allow me to give your readers a full explanation.
>
> In the first place I may tell you that I instructed my counsel, Mr. Avory, K.C., to admit that I had committed a technical offence, as my manager had omitted to add "U.S.A." after my M.D. degree when he sent the bill matter to the Camberwell Palace of Varieties. Still this omission does not take away the fact that I am a duly-qualified M.D. of a recognised university of America, chartered by the United States Government to confer degrees—a university of which several of our biggest practitioners hold degrees, the college in question being the Barrett College, Carolina, U.S.A. I hold my diplomas from said college as M.D. (Doctor of Medicine) and C.M. (Master of Surgery). I also hold diploma as D.Ph. (Doctor of Philosophy) and D.Sc. (Doctor of Science) and Medical Electric Therapeutics of the Chicago College of Medicine and Surgery. My English degrees and titles are are follows: F.R.C.I. (Fellow of the Royal Colonial Institute, London), F.R.M.S. (Fellow of the Royal Meteorological Society, London), F.R.W.S.M. (Fellow of the Royal Worshipful Company of Spectacle Makers, London), F.S.Sc. (Fellow of the Society of Arts, Letters and Literature of London), M.S.A. (Member of the Society of Arts, London), of which society the Prince of Wales is president, the last to receive the honorary title being the King of Spain.
>
> I have also attended the Guildhall, London, and have paid my fee and been nominated, and hope, when I return to town, to be granted the freedom of the City of London, my name on the list being next to Lord Curzon's. I was elected F.R.C.I. along with Lord Tennyson and several other men of note, so you will see, sir, that, in my short professional career, I have done nothing that any of my fellow-townsmen need be ashamed of. I have tried to uphold the dignity of my country and my native town; and I think, sir, that as a young man, you must admit I have been fairly successful. The sensation I have created in the great metropolis as a public demonstrator of the science of hypnotism, electricity, and bloodless surgery has been admitted by the press and public of London to be unprecedented.
>
> I return to London in October and am booked at all the leading West-End halls at the biggest salary ever paid to any artiste, and also specially engaged by Oswald Stoll, Esq., of the Coliseum, London, to appear at all his Empires, &c.
>
> And, now, sir, as you are a lover of fair play and having a little claim on you as a native of the Granite City, I trust you will kindly grant me space in your widely-read paper to insert this letter to show my fellow-townsmen my true position under the circumstances.—Thanking you in anticipation,
>
> I am, &c.,
> Walford Bodie,
> M.D., C.M., D.Ph., D.Sc., U.S.A.; F.R.C.I.,
> F.R.M.S., M.S.A. Lond.
>
> 11, Arundel-place, Leicester-square, London, July 12th, 1905.
>
> P.S.—Your report did not state that I was so pleased with the magistrate's decision that, in addition to the fine, I handed the clerk of the court £5 for the poor-box.

Re the above, Mr. P. J. Anderson, M.A., LL.B., librarian, University of Aberdeen, says in the course of a letter published by our contemporary on July 15th:—

> "As this is not the first occasion on which a 'degree' of 'Barrett College' has been obtruded on the notice of the readers of the *Express* it seems fitting to give publicity to the appended deliverance on the subject by the Commissioner of Education of the United States: 'The name of Barrett College in North Carolina does not appear on any of the lists of educational institutions published by this office and I have no information concerning it. The Barrett College and Industrial Institute at Pee Dee, North Carolina, is an institution for the education of coloured persons. All of its teachers are of the coloured race and it does not have any students in college classes. ...... The institution is classed as a secondary school.'"

GARBAGE FOR THE CONSUMPTION OF CHILDREN.

Salvatore Alloca, described as an ice-cream manufacturer, was ordered recently at Deptford police-court to pay fines amounting to £3, with 4*s.* costs, for storing "ice-cream" on premises which were in a dirty and insanitary state and for causing "ice-cream" to be manufactured in a room used as a living room. The evidence showed that in the room where the concoction was manufactured meals were eaten and as many as six men at a time smoked their pipes. The evidence of the medical officer of health dealt with the place of storage where he had seen cans of milk standing. It consisted of a small shed opening on to a yard with broken pavement and with water standing in the crevices. It was shown, also, that the defendant had previously been convicted of a similar offence. Prepared under the best conditions conceivable the "ice cream" sold to children in halfpennyworths from barrows in the street can scarcely be anything but an unwholesome mess and it would be a benefit rather than a loss to the community if its sale were forbidden altogether or subjected to such continual restrictions of inspection and analysis as to render a profitable trade in it impossible. Wise parents reading the reports of such cases as that referred to will forbid their children to buy "halfpenny licks" and will refuse to provide them with money to purchase such indulgences.

A MISLEADING DESCRIPTION.

To the Editors of The Lancet.

Sirs,—A firm of surgical instrument makers, Messrs. Hockin, Wilson, and Co., of 13 to 16, New Inn Yard, Tottenham-court-road, London, W., has been advertising and sending round a pamphlet advertising an all-metal hypodermic syringe of five minims capacity. A hypodermic syringe of that capacity would be a desirable instrument, the capacity being the usual recognised dose. I obtained one and a fortnight afterwards had occasion to use it when I found to my surprise that the syringe, which is not graduated, contained not five minims as stated, but ten minims or more. The result was an almost fatal effect to the patient. After testing the capacity of the syringe I at once wrote to Messrs. Hockin, Wilson, and Co., and their reply was that the error was made in printing their circular and that they much regretted it. Upon receiving their letter I suggested that they should let the press know to whom they had supplied the syringes and their reply was that they could not send another circular round. As this might have a serious result, in the interest of the medical profession and of the public, I feel bound to write this letter to you and the other medical papers to call attention to it.

I am, Sirs, yours faithfully,
Arthur Joseph O'Leary,
Honorary Anæsthetist, Liverpool Royal Infirmary.
Liverpool, July 22nd, 1905.

FASHIONABLE INTELLIGENCE!

To the Editors of The Lancet.

Sirs,—The following notice appears in the *Daily Telegraph* of to-day.

> "Dr. John H. Clarke, of 8, Bolton-street, Piccadilly, will leave London on Saturday next, August 5th, for Walcot, Norwich. He will be absent until August 30th."

I cannot think that the movements of Dr. Clarke or of any other practitioner should be publicly notified as above.

I am, Sirs, yours faithfully,
August 1st, 1905. Innocence.

⁂ Such a notice is much to be deprecated.—Ed. L.

MEDICAL WITNESSES AT CORONERS' INQUESTS.

To the Editors of The Lancet.

Sirs,—Are honorary medical officers to a hospital entitled to a fee for giving evidence before coroners in cases where the death takes place in the hospital, or does the Act only apply to paid medical officers? Thanking you in advance, I am, Sirs, yours faithfully,
July 29th, 1905. S. J.

⁂ The section of the Coroners Act dealing with the question our correspondent asks is Section 22. After mentioning the fees payable in the case of giving evidence at an inquest without making a post-mortem examination and for giving evidence as well as having made a post-mortem examination, the section goes on to state: "Where an inquest is held on the body of a person who has died in a county or other lunatic asylum, or in a public hospital, infirmary, or other medical institution, or in a building or place belonging thereto, or used for the reception of the patients thereof, whether the same be supported by endowments or by voluntary subscriptions, the medical officer, whose duty it may have been to attend the deceased person as a medical officer of such institution as aforesaid, shall not be entitled to such fee or remuneration."—Ed. L.

BOVININE AS A DRESSING.

To the Editors of The Lancet.

Sirs,—A gentleman who was under my care recently had suffered from very extensive necrosis of the right tibia. This when I saw him was completely healed, a deep furrow extending practically the whole length of the bone being present, the bottom of which was covered by thin shiny skin. The interest of the case lies in the point that, according to his statement, and I have no reason to doubt him, this healing process was brought about by means of bovinine, an extract of beef, with which it had been freely dressed. He told me that this preparation is extensively used in the United States (where he had been staying) as a dressing for callous cavities such as his, indolent ulcerating surfaces, &c. Whilst under my observation his scar broke down at its lower part, but was induced rapidly to heal by the above means. One feels tempted to inquire whether the meat extract acts as a phagocytic nutrient or merely as a stimulant to granulation formation; at any rate, it seems worthy of trial in suitable cases. I pen this note with some diffidence, for though new to me the subject-matter may be well known to others.

I am, Sirs, yours faithfully,
C. Francis Steele, M.B. Lond.
Matlock.

◆

J. V.—Our correspondent, though not medical, takes such an intelligent interest in the problem that we advise her to send a subscription to the Cancer Research Fund, Laboratory of the Conjoint Board, Thames Embankment, W.C., and ascertain what has been done by that fund.

The Croonian Lectures

ON

THE CHEMICAL CORRELATION OF THE FUNCTIONS OF THE BODY.

Delivered before the Royal College of Physicians of London on June 20th, 22nd, 27th, and 29th, 1905,

BY ERNEST HENRY STARLING, M.D. LOND., F.R.S.,
FELLOW OF THE COLLEGE; JODRELL PROFESSOR OF PHYSIOLOGY, UNIVERSITY COLLEGE, LONDON.

LECTURE II.[1]

Delivered on June 22nd.

THE CHEMICAL REFLEXES OF THE ALIMENTARY TRACT.

MR. PRESIDENT AND GENTLEMEN,—With the first appearance of multicellular animals and the setting apart of a distinct layer of cells, the hypoblast, for digestion and assimilation the activity of the cells is at first largely analogous to that of the previous unicellular organisms, each cell of the alimentary epithelium seizing and ingesting the food particles which reach the cavity of which the cells are a lining. The digestion is therefore at first largely intracellular and the ingestion of food particles must be determined partly by chemical and partly by tactile or mechanical stimuli arising in the food particles themselves. In the lowest of metazoa, however, cells are found which exercise their influence on external organisms by the production and excretion of poisonous material and a similar mechanism is soon evolved in the alimentary tract for the production of digestive fluids. An elementary type of digestive apparatus would therefore be a cavity lined with epithelial cells which are stimulated to the secretion of digestive juices by the chemical and mechanical stimuli arising from food which has been introduced into the cavity. The increase in these digestive cells necessitated by the greater bulk and greater activity of the animal arising with the elevation in type is procured in all the higher animals by the formation of outgrowths of cells from the lumen of the alimentary canal, outgrowths which give rise to the structures which we know as glands. The cells composing these glands are no longer subject to direct stimulation by any food present in the alimentary canal. Each act of secretion of digestive juices must therefore involve the transmission of a message of some sort or other from the lining epithelium of the alimentary canal to the gland in question—a transmission which is apparently analogous in all respects to the mechanism for the production of movements in response to external stimulation. In the higher animals all the motor reactions affecting skeletal muscles are carried out by reflex actions and involve the coöperation of the central nervous system. It is natural to suppose that the similar reactions affecting the chemical activity of glands should be carried out in the same way and the earliest investigations of the influence of the nervous system on glandular activity corroborated in all respects this supposition. The taking of food into the mouth, for instance, is at once followed by a flow of saliva due to an induced activity of the various salivary glands. This reaction was studied by Ludwig in the first half of the last century and the experiments of this investigator showed conclusively that the normal path for the message from mucous membrane of mouth to gland lay through the central nervous system. The nerves involved in the reflex secretion of saliva were determined, as well as their central connexions. In such a case as this, where all kinds of material—dry, fluid, pleasant, or harmful—may be taken into the mouth, a rapid response of the salivary glands is necessary to provide for the speedy swallowing of the food or to facilitate its expulsion from the mouth. When the food has once undergone a preliminary warming and moistening in the mouth and has been passed, so to speak, by the critical organs of taste and smell placed at the commencement of the alimentary tract a rapid reaction of the other glands of the alimentary canal—i.e., one occupying fractions of a second—would not seem to be absolutely necessary. The predominant part, however, played by the central nervous system in all the most direct reactive phenomena of the body led physiologists to search for similar reflex nervous mechanisms of secretion through the rest of the alimentary canal, and the firm faith that such nervous mechanisms existed was in no way damped by the difficulties experienced in the attempts to determine their existence and their paths. Thus for many years the only known method of exciting gastric secretion was the introduction of irritant substances into the stomach, apart, that is to say, from the taking of a meal which would excite in physiological fashion a secretion of gastric juice. In the case of the pancreas Heidenhain observed on a few occasions a scanty secretion from stimulation of the medulla oblongata but could not obtain this result at will. Succus entericus was obtained by some observers from intestinal fistulæ by mechanical stimulation of the mucous membrane and the so-called paralytic secretion of succus entericus was produced in certain circumstances in a denervated loop of intestine.

These were the sole indications of any influence of the nervous system on the secretions below the mouth until the subject was taken up by Pawlow at St. Petersburg. This observer realised that the last word could not be said on any physiological question until experiments had been made on an animal in an absolutely physiological condition—i.e., with normal blood pressure, free from fear or pain, and unpoisoned by anæsthetics. To effect this aim Pawlow has enriched physiologists with a new technique. By the exercise of scrupulous asepsis, and aided by his great surgical skill, he has succeeded in making observations on the digestive process in animals by providing them with fistulous openings into different parts of the alimentary canal, or with culs-de-sac which were in nervous and vascular continuity with the rest of the canal and whose activity could be taken as samples of the activity of the whole organ from which they were cut off. The results obtained by this physiologist seem at first to point to an extension throughout the alimentary canal of processes similar to those occurring in the mouth and to prove that every gland in the canal is excited reflexly through the central nervous system by the presence of the foodstuffs in different stages of digestion at the appropriate part of the lumen of the canal.

Thus the mere sight of food or the taking of pleasant food into the mouth excites reflexly through the vagi a reflex secretion of gastric juice and this secretion can be also evoked by artificial stimulation of the peripheral end of a cut vagus. The passage of acid chyme, of water, or oil, from the stomach into the duodenum excites the flow of pancreatic juice, the efferent channels, according to Pawlow, for the reflex being both the vagi and the splanchnic nerves, since secretion of pancreatic juice can be evoked by stimulation of either of these nerves. The secretion of succus entericus is less distinctly due to the intervention of a distant nervous system, since it is evoked in two circumstances—namely, (1) mechanical distension of the gut; and (2) introduction of inert pancreatic juice.

Previously to the publication of Pawlow's results no physiologist had succeeded in obtaining an invariable secretion of either gastric or pancreatic juice as the result of stimulation of any nerves. A few years after the description by Pawlow of the production of pancreatic secretion by stimulation at some point in the long reflex path—viz., from intestinal mucous membrane, through medulla and vagus or splanchnics to pancreas—it was shown by Wertheimer in France and by Popielski in Russia that the introduction of acid into the duodenum evoked a reflex flow of pancreatic juice even after division of the vagi and splanchnics or complete destruction of the spinal cord. These observers, therefore, regarded the reaction as belonging to the type of peripheral reflexes, the centre being located by them in the ganglion cells, somewhere in the wall of the intestine or the pancreas itself. Previous observations by Bayliss and myself had shown that the normal peristaltic movement of the intestine was a peripheral reflex, the paths of which lay wholly within the walls of the alimentary canal; and we were therefore interested to determine the conditions of the similar supposed reflex affecting the glandular activity of the pancreatic outgrowth of the canal. A few experiments sufficed to show that the so-called peripheral reflex secretion of pancreatic juice evoked by the introduction of acid into the duodenum or upper part of the small

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents

Agent for the Advertisement Department in France—J. ASTIER, 31 Rue Bapts, Asnieres. Paris.

answer to this question we are inclined to believe that the chemical mechanism is the only one involved in the secretion of pancreatic juice and that in all Pawlow's experiments where secretion was excited by the stimulation of nerves such as the vagus or splanchnics the effect on the pancreas was really a secondary one due to movements of the stomach arising as a result of the nerve stimulation and squeezing some of its acid contents into the first part of the small intestine. Other workers, however, such as Fleig and Wertheimer, believed that both mechanisms are at work—namely, that through the mucous membrane of the intestine the pancreas can be excited to secrete by both nervous and chemical means. We ourselves have never been able by nervous means to obtain secretion of pancreatic juice provided that we excluded all possibility of entry of acid into the upper part of the small intestine.

The discovery of this simple chemical nexus between alimentary canal and pancreas suggests at once the possibility of other mechanisms of the same description taking part in the complex chain of events involved in the digestion of our foodstuffs. Investigations on this point, carried out partly in my laboratory and partly by independent observers, have shown this belief to be justified and I propose in my third lecture to deal with the facts at present ascertained which point to a whole chain of such chemical reflexes throughout the alimentary tract.

NOTES ON AFRICAN PYGMIES.

BY G. ELLIOT SMITH, M.A. CANTAB., M.D., CH.M. SYD.,
FELLOW OF ST. JOHN'S COLLEGE, CAMBRIDGE; PROFESSOR OF ANATOMY IN THE EGYPTIAN GOVERNMENT SCHOOL OF MEDICINE, CAIRO; MEMBRE DE L'INSTITUT EGYPTIEN.

With a Note on Intestinal Worms found in African Pygmies by Dr. A. LOOSS, *Professor of Parasitology, the School of Medicine, Cairo.*

DURING their sojourn of the greater part of a month in Cairo the party of six pygmies brought by Colonel Harrison from the Ituri Forest in the Congo Free State lived in the School of Medicine and the adjoining Kasr-el-Aini Hospital where they were treated for the interesting form of ankylostomiasis described by Professor Looss in the note which accompanies this account. During the whole of this time the pygmies practically lived in the anatomical department of the School of Medicine, so that I have had ample opportunities for examining them and studying their behaviour. With the full consent of Colonel Harrison I have made a large series of measurements and have had numerous photographs and skiagrams made. For the excellent series of skiagrams used in this investigation I am indebted to Dr. Khayatt and I have to thank Mr. Herbert M. Nelson Milton for permitting these photographs to be taken in the Victoria Nursing Home.

Although the literature relating to pygmies is now quite voluminous I make no apology for adding these notes, scanty as they are, because they will clear away some of the confusion arising from the many conflicting statements and the errors of observation recorded in the earlier accounts. The arrival of these six individuals has afforded most of us who have seen them the opportunity of becoming personally acquainted for the first time with a race long known to us in fable and what has often been supposed to be a mere tradition as old as the oldest human civilisation—a race, moreover, of the greatest biological interest as being the smallest of mankind. The ancient history of this race has been so often and so fully discussed—whole treatises such as that written by De Quatrefages (1887) have been devoted to the subject—that it would be quite unnecessary to attempt to deal with this aspect of the question at any length. There are, however, one or two of the most crucial problems in the disputed interpretations of these early records that seem to be solved by the information now available.

It is not infrequently supposed that this is the first visit of any members of the true pygmy race to Egypt (or Europe), but this idea is quite erroneous, as everyone acquainted with the writings of Professor Schweinfurth, Sir William Flower, and Professor Stuhlmann must be aware. These little people have been preceded by several parties of their kinsmen within recent years and probably by numerous representatives of their race in ancient times. Professor Schweinfurth discovered (or rather rediscovered after a lapse of two centuries) the Akka pygmies in the Monbuttu country in 1870[1] and obtained from Munza (the king of the Monbuttu) an Akka boy in exchange for a dog. This boy died at Berber on his way to Egypt as the result, so Professor Schweinfurth tells me, of an excessive meal of macaroni. (I should mention here that in the study of these pygmies I have had the help of Professor Schweinfurth who also kindly gave me a most useful photograph of a group of 23 Mbute pygmies taken in their native Semliki forest by Dr. J. David last year.) The Italian traveller Miani was more successful in accomplishing his purpose of sending pygmies to Europe, although he himself succumbed in the effort. In the writings of Professor Schweinfurth and Sir William Flower[2] is a full account of all that Miani's two Akka boys had to submit to at the hands of a swarm of enthusiastic European anthropologists and others in Cairo and afterwards in Verona and other parts of Italy. In 1876 another Italian, Gessi Pacha, who was one of Gordon's lieutenants in the Soudan before the Mahdist rebellion, obtained in the Bahr-el-Gebel a slave girl who was supposed to belong to the Akka race and took her to Trieste, where she was living in 1888 as a servant to Madame Gessi. But according to Mateucci[3] the racial purity of this girl is open to question. In 1893 Dr. Stuhlmann is said to have taken two dwarfs from the Ituri river to Germany.[4]

Amongst the heterogeneous population of Cairo there are found representatives of almost all the Nilotic and even central African tribes. Many of these people have been slaves who have been recaptured from their captors and liberated by the Government's agents. It thus happens that the unclaimed bodies of persons dying in the Kasr-el-Aini Hospital in Cairo which eventually come to the anatomical department of the School of Medicine, include the most varied assortment of Nilotic peoples. Within the last three years the bodies of two small Negroid women, one 1436 millimetres in height and the other slightly smaller, have been dissected in my department. They presented none of the mutilations of face, teeth, and pudenda which are almost invariably—at least, so far as the genital organs are concerned—found in Nilotic Soudanese women; in the proportions of their limbs, the form of their heads and lips, and in many other respects, they closely resembled the Negritoes. But as nothing was known of their provenance and as their noses lacked that peculiar development of the alæ nasi which at that time I imagined to be the invariable characteristic of true pygmies, I came to the conclusion that they could not belong to that group; and as their nature was so uncertain I did not devote to their study that amount of attention which I should have done had I known, as the examination of this group of pygmies has shown me, that their facial features might well be (and probably are) those of true pygmies. However, as a matter of routine I fully examined their skeletons and brains and the students who dissected the bodies have recorded a number of departures from the normal structure of the body. From the characters of the skeletons I believe that these two individuals belonged to the group of Equatorial African pygmies whose osteological features have been described by the late Sir William Flower[5] and Dr. Frank C. Shrubsall.[6] I shall refer to the structure of these individuals further on in this account. I refer to the matter now to indicate the possibility or probability that true pygmies may reach this country by other means than the agency of European travellers.

The fact that some of the pygmy people now live in close proximity to the sources of the Nile and that, according to those anthropologists who have studied the question on the spot, their domain probably extended over a much wider area in former times, renders it highly probable that at various times the ancient dwellers on the banks of that river may have heard, or perhaps even seen, some of these little people in the course of their numerous expeditions to the south. But even if this fact were established with absolute certainty it would not justify us in intestine occurred absolutely independently of any nervous channels whatsoever and that it was possible to isolate the pancreas from the duodenum, to divide all the nerves going to a loop of the small intestine, and then by injection of acid into this loop to evoke secretion of pancreatic juice. Further observations showed us that the reaction instead of being nervous was in reality a chemical one. The entry of acid into the duodenum or upper part of the small intestine causes the production in the mucous membrane of a chemical substance which we call secretin. Since, as I shall show later, there are other secretins, we may speak of this as the pancreatic secretin. This pancreatic secretin is rapidly absorbed into the blood and travels with the blood to the gland, the cells of which it excites to secrete.

---

[6] Sir Harry Johnston's "Uganda Protectorate," vol. ii.

In order to obtain secretin the method we have always adopted has been to scrape off the mucous membrane of the duodenum and upper two feet of the small intestine, to pound this up in a mortar with sand with the addition of 0·4 per cent. hydrochloric acid and then to boil the mixture over a free flame, the liquid when boiled being neutralised with caustic potash. All the proteids of the decoction are precipitated and if the mixture be thrown on a filter a clear fluid filters through. This fluid contains the secretin. In order further to free it from traces of gelatin and proteid it may be precipitated by absolute alcohol and ether; the secretin is not thrown down and can be recovered from the alcohol-ether solution by evaporation of the latter. A few cubic centimetres of the original filtrate from the boiled mucous membrane or of a watery extract of the residue left on evaporating the alcohol-ether solution on injection into the veins of an animal evoke a plentiful secretion of clear pancreatic juice which can be collected by means of a cannula placed in the duct of the gland. The secretin can be obtained in this way from the upper part of the intestine of any member of the vertebrata and a solution of secretin obtained from any animal will on injection into any other animal evoke a secretion in the latter of pancreatic juice. We have, therefore, in secretin a substance of the same general distribution as adrenalin, which, like this latter, is unaltered by boiling, is soluble in alcohol, and, as we have determined by direct experiments, is more or less diffusible. Although secretin has not been further isolated and we have therefore no clue as to its chemical characters there can be little doubt that it belongs, like adrenalin, to the drug class of substances which exercise an influence on the physiological workings of the body. The limited seat of production of secretin and the definite response evoked by its injection determine a chemical reflex which is as adapted to the needs of the organism as are the muscular reflexes carried out by the central nervous system. The acid chyme entering the duodenum excites the formation of secretin in the mucous membrane, which in its turn causes a flow of alkaline pancreatic juice. The formation and absorption of secretin will proceed until the chyme is exactly neutralised by the alkaline juice. As soon as this neutralisation occurs the pyloric sphincter, which remains firmly closed so long as the duodenal contents are acid, opens and allows the entry of a fresh portion of acid gastric contents which in their turn will, through the secretin mechanism, call forth a secretion of an exactly corresponding amount of pancreatic juice. It is thus contrived that the further digestion of the foodstuffs in the small intestine will proceed in a medium which is approximately neutral and is at any rate free from any trace of mineral acid.

We may next inquire into the manner in which the contact of acid can give rise to the production of secretin in the mucous membrane. It seems most probable that the action of acid is one of hydrolysis, since although various acids can be used for the preparation of secretin their efficacy is more or less proportional to their strength or rather to their acidity, a weak acid such as boracic having no influence on the production of secretin. Bayliss and I have suggested therefore that the epithelial cells lining the upper part of the small intestine contain a substance, pro-secretin, from which by hydrolytic agents secretin can be split off. This precursor of secretin is quite insoluble since we have been unable to obtain secretin by the actions of acids on filtered extracts of the mucous membrane. It is not destroyed by the death of the cell, since secretin may be obtained by the action of acid upon boiled mucous membrane or upon mucous membrane which has been repeatedly extracted with absolute alcohol and then dried. On the other hand, if the process by which secretin is formed is hydrolytic this change must be able to be effected by the living cells in the absence of such strong hydrolytic agents as dilute hydrochloric acid. Thus Fleig has shown that a secretin similar in all respects to that described can be obtained by the action of soaps on the mucous membrane; and there is no doubt that a similar substance is produced in the mucous membrane and absorbed into the blood when such substances as ether, chloral, or oil of mustard are introduced into the lumen of the gut. It is difficult to imagine that any of these substances can exercise a direct hydrolytic effect and it is certainly impossible by their means to extract secretin from a mucous membrane which has been already killed.

That the secretin formed in the mucous membrane actually gets to the pancreas by way of the blood stream has been shown by Wertheimer. This observer led the blood from the intestinal veins of one dog (A) into the blood stream of a second dog (B) and found that injection of dilute acid into the intestine of dog A evoked a secretion of pancreatic juice in dog B. Although the view given above as to the origin of secretin is most probably correct our failure up to the present to isolate pro-secretin in any way from the mucous membrane forbids us to accept the theory as definitely established. Delezenne has found that digestion of a solution of secretin with a fresh extract of intestinal mucous membrane deprives the secretin of its efficacy. He has therefore advanced the suggestion that secretin is really preformed in the wall of the gut but is accompanied by another body, its physiological antagonist, which he denotes by the name of anti secretin. He imagines that the action of acid is to destroy the anti-secretin, thus unmasking the action of the secretin. The fact, however, that secretin, which is extremely soluble both in water and fairly strong alcohol, is not extracted in any appreciable quantity by these fluids from the mucous membrane until acid has been added is difficult to reconcile with Delezenne's suggestion; moreover, the general characters of secretin, its resistance to proteid-precipitating agents, and so on, point to it as belonging to a class of bodies which would not give rise to anti-bodies when introduced into the organism.

As to the mechanism by which secretin arouses the activity of the pancreatic cells, the expulsion of its preformed ferment or pro-ferments, together with the building up of new protoplasm and ferments which always accompanies normal activity, we have little or no conception. Early in our researches the suggestion was made to us by Dr. A. Walker that the secretion of pancreatic juice was of the nature of the formation of an antibody to the secretin. That this explanation will not hold is shown by the fact that secretin is equally efficacious when it is mixed with a large quantity of fresh pancreatic juice. If, however, the pancreatic juice be activated by the addition of succus entericus so that its trypsinogen is converted into trypsin, it has the power of destroying the secretin. Moreover, as I mentioned in my last lecture, such a localised formation and excretion of an antibody has no analogue among the facts hitherto brought to light by bacteriologists as to the formation of antibodies in general. We are inclined to think that the action of secretin is that of a specific drug—that just as pilocarpin acts on all the glands of the body, including the pancreas, so secretin acts on the pancreas with, perhaps, one or two other glands which are associated with the pancreas in their functions. Its action is not, however, identical with that of pilocarpin. The latter drug induces in the pancreas the secretion of a thick viscid juice containing from 7 to 8 per cent. of solids. Its action is entirely abolished by the injection of a small dose of atropin. On the other hand, secretin produces a juice containing about 3 per cent. of solids, which resembles in every particular the juice obtained from an animal with a pancreatic fistula after it has received food. Its action is not altered in any way by the previous injection of, at any rate, moderate doses of atropin.

The discovery of this chemical reflex which is sufficient to explain the correlation of activities between the mucous membrane of the small intestine and the pancreas must cause us to inquire how far these results are to be reconciled with the previous results obtained by Pawlow. According to Pawlow's original idea the reflex secretion of pancreatic juice was entirely nervous. The question now arises whether both mechanisms function in normal circumstances or whether it is possible to explain all Pawlow's results by the chemical mechanism which I have described. Although we cannot at the present time give a definite the Guinea Coast. These accounts met with little credence at the time and at the beginning of the nineteenth century these stories with those of the classical writers were relegated to the domain of fairy tales. With the growth of a fuller knowledge of natural history and of a more critical inquiry into the facts of nature and the records of history all of these reports were "explained away" as mere travellers' tales or as highly coloured accounts of tribes of apes and monkeys. But from the middle of the nineteenth century onwards numerous travellers in various parts of Equatorial Africa and its neighbourhood began once more to record reports which they had heard of diminutive races of men. Dr. Touchard (1861) and Admiral Fleuriot de Langle (1868) described the rapid extinction of a pygmy race in the Gaboon region. M. Paul du Chaillu (1867) in penetrating the forest behind the French possessions in West Africa came upon a pygmy race in Ashongoland between the Gaboon and Congo rivers. Speke and, at a later period, Stanley (1876) heard of the Batwa or Watwa pygmies along the upper waters of the Congo, whom Lieutenant Wissmann and Dr. Wolff met and described in 1887.

The Akka dwarfs seen by Dapper were rediscovered by Professor Schweinfurth two centuries later (1870) and have been seen by the Italian geographer Miani, by Emin Pasha and Stanley, by Stuhlmann and several others. Several of these people have been studied both in Africa and in Europe, and the skeletons of two of them, sent to England by Emin Pasha, have been fully described by the late Sir William Flower. The late Sir Henry Stanley, and more recently Sir Harry Johnston and Dr. David have seen the Mbute (Bambute, Wambutti) pygmies. They are said to live in a territory further west, near the Uganda frontier; but it is very doubtful whether there is any distinction between the Akkas and the Mbute. Stuhlmann says that among the neighbouring tribes the name Akka is often applied to the Mbute. When I questioned the chief of Colonel Harrison's party as to the name of his people he called them "(M)Akkaba." It is highly probable that the names Mbute, Akka, and Batwa are little more than geographical terms without any ethnological significance. In his work on the "Uganda Protectorate" Sir Harry Johnston gives a very full account of the pygmies and describes a more widely scattered negroid population composed of small people scattered amongst the larger negroes. These he calls the "pygmy-prognathous" group and regards as distinct from the true pygmies, although Dr. Shrubsall, who has written a report on Johnston's anthropological data, considers that they exhibit signs of affinity with the pygmies. As Sir Harry Johnston describes the unions which take place between men of neighbouring tribes and pygmy women it is perhaps not surprising to find a scattered population of small negroids beyond the pygmy domain.

The age of the individuals.—In discussing the size and relative proportions of the body in pygmy people the question of the age of the individuals studied is of the utmost importance, for all our conclusions may be vitiated if we treat the mensurations of children as those of adults. It is therefore desirable to study the problem of the determination of the ages with the utmost care. As the people themselves have no ideas whatsoever of their age and the statements made concerning them are obviously mere guesswork of the crudest description,[11] we can at the outset put aside all preconceived ideas as to their ages and study the question on the evidence afforded by the state of their teeth and bones. The value of the evidence afforded by the teeth is not so great as that of the osseous tissues, because the dates of eruption of the former are liable to great variation. There is no doubt that there is a definite tendency amongst the African people for the teeth to cut the gums at an earlier period than in Europeans. It is difficult to obtain definite information in support of this contention because so few people in Egypt and the neighbouring countries have any idea of their exact ages or of those of their relatives. It is a common occurrence for the third molar teeth in Egyptians to cut the gums before the eighteenth year and cases in which these teeth had erupted as early as the fourteenth (and even the thirteenth, according to Dr. Harold Nolan) year have been met with. With reference to the second molar teeth I am unable to make any statement as to the date of eruption from my own knowledge, but my friend, Dr. Nolan, who has had occasion frequently to examine the teeth for medico-legal purposes, has the idea that these also (and, in fact, all the teeth) are precocious, judged by the European standard. The difficulty of ascertaining the exact age in all except the rarest cases has so far rendered it impossible to make any more definite statement regarding this important subject.

The party of pygmies with whom we are at present concerned consists of six individuals, four of whom are males and two females. Of the men only one—the chief, Bohani (or Morgany)—had cut his wisdom teeth and that had happened many years ago. He had lost many of his front teeth: his third molars had the same form and were almost as large as the other molars. He had a long oval palate and the teeth were big. The youth Mafutiminga had not yet cut his third molar teeth. His molars were bigger than those of the others. There was a large gap, 6·5 millimetres, between the two median incisors placed chiefly on the left side of the mesial plane. Judged by the Egyptian standard there is the possibility that a youth who had not cut his third molar teeth may not yet be 18 years of age, if as much. The third male, named Matuha, had not yet cut any of his wisdom teeth and the boy Mongungu had not only not cut his wisdom teeth but the crowns of the second molars were elaborately sculptured and obviously new as though recently erupted and the gums around these teeth were still red from the irritation caused by the tooth breaking through. In Europeans this is supposed to take place in the twelfth year. There was a distinct hiatus between the canine and second incisor teeth, which probably indicated that the canine had not yet been pushed up to its full height. In other words, the canine which cuts the gum during the eleventh year in Europeans had not yet finished growing—i.e., had only recently erupted in this boy. So that even judged by the European standards the evidence of this boy's teeth points to the fact that he is no more than 12, or perhaps even 11, years of age. Of the two females, one—Amooriape—is an old woman with a complete set of well-worn teeth; in fact, judged by her teeth she is much the oldest of the party and may be 40 or 50 years of age. The other woman—Kuarhe—also has a complete set of teeth, but her third molars appeared to have only recently erupted. With the object of throwing further light upon the problem of the determination of their ages Dr. Khayatt made skiagrams of the hands and wrists of the whole party and of the elbow in the cases of Matuha and Mongungu. It had been our intention during the last few days of the pygmies' stay in Cairo to submit all parts of the skeletons (of all of them) to examination by the Roentgen rays, but the interruptions caused by their treatment for ankylostomiasis and their sudden departure two days before it was expected interfered with this plan. At the same time, we have been able to obtain sufficient data to enable us to estimate their age by European standards. In the cases of the man Bohani and the old woman Amooriape the bones of the hand and wrist were perfectly ossified, but in the other four individuals the skeleton exhibited various stages of immaturity.

I shall begin with the consideration of the youngest of the party, Mongungu. Skiagrams show that the proximal extremities of all the phalanges of both hands are still widely separated from the shafts. The proximal end of the metacarpal of the thumb is separated from the shaft by a gap of a similar extent to that of the phalanges. In this respect it presents a marked contrast to the epiphyses for the heads of the other four metacarpals, the line of separation of these from their shafts being hardly visible in the right hand and not at all—if we ignore some doubtful traces of the epiphyseal line in the second and third metacarpals—in the left hand. If these epiphyses have really joined their shafts—there is, of course, the possibility that a slight obliquity of the bones may have caused the narrow epiphyseal gap to be hidden—it is a most extraordinarily precocious development; but it cannot be distinctive of all pygmies (at any rate, the date of union cannot be so very early) because in the much older boy Matuha the epiphyseal gaps in the metacarpals are distinct in the left hand although they are almost closed in the second, third, and fourth metacarpals of the right hand. In Matuha's right hand the epiphysis of the fifth metacarpal seems to be perfectly fused to its shaft, although the epiphyseal gap is quite open in the corresponding finger of the left hand. All of the phalangeal and metacarpal bones in Mongungu's hands still retain their infantile shapes and in this respect present a marked contrast to all the other concluding, as so many recent writers have done, that every mention of small men in the ancient Egyptian writings referred to real pygmies. On the contrary, we know for certain that at all times in Egyptian history (from the earliest period of which we have any records even up to the present time when His Highness the present Khedive has a dwarf at the Koubbeh Palace who is an honoured sheikh and story-teller) dwarfs have been received with special favour at the court of the ruler of Egypt and have had posts of honour accorded them. Most writers fail to draw a proper distinction between *dwarfs* and *pygmies*—i.e., between those instances of diminutive stature which may occur in any race as the result of pathological causes or, perhaps occasionally, as the mere extreme of variability in size without any definite pathological reason and the smallness which distinguishes a whole population. The diminution of the stature in the former class may be the result of a reduction in size of all parts of the body—true or total nanism or it may be partial—affecting only some parts, so that the body is misshapen and distorted. Many of the representations of dwarfs in the ancient Egyptian wall pictures and statues suggest this partial nanism, but it is quite possible that the idea of the small size and the figure of a dwarf were conveyed by exaggerating the distortion of the body which the actual dwarf presented. Size of body in an ancient Egyptian picture was so often used to represent relative importance of individuals that the mere diminution in size would not necessarily convey the idea of a dwarf, so that something more was necessary—some distortion of the body—to suggest nanism in a picture. It is quite possible that this may be the explanation of the representation of all dwarfs as exhibiting the misshapen head and form of one particular variety of nanism. Perhaps the best Egyptian representation of a dwarf is the statue of the dwarf Khnumhotpu in the Cairo Museum (represented also in Maspero's "Dawn of Civilisation," p. 280). In this statue the idea of "dwarfishness" is conveyed by the plumpness of all parts of the limbs and body and the shape of the head. Professor Maspero, the director-general of the Egyptian Service des Antiquités, tells me that a careful study of all the passages in ancient Egyptian literature which have been supposed to refer to pygmies fails to reveal a single instance of a description which can justify such a belief. The determinative invariably applied to these supposed pygmies is a hieroglyphic sign representing the misshapen figure expressive of partial nanism. Professor Maspero refuses to admit that this hieroglyph may be a conventional sign applied to all persons of diminutive stature. It seems to me highly improbable that all dwarfs should possess a figure in any way resembling the sign invariably used to indicate "dwarfishness"; and if this sign can be applied to a well-proportioned dwarf may it not also be used to indicate a pygmy? I make this suggestion only because it offers a possible explanation of a passage which may be the first historical record of the true Negritoes of Equatorial Africa. In Professor Schiaparelli's memoir, "Una Tomba Egiziana inedita della VIª dinastia," published in Rome in 1893 (for my information regarding this memoir I am indebted to the writings of Maspero, Keane, and Sergi), there is an account of some small people brought to Egypt about 3000 years B.C., which is difficult or impossible to explain unless we admit that it refers to the real pygmy Negritoes.

---

[11] A boy of the party who had not reached the state of puberty and whose gums were still red from the irritation caused by the eruption of the second upper molar teeth was said to be 18 years of age.

Somewhere to the south of Egypt was the far-famed land of Punt, a geographical term which has received innumerable explanations. It is clear, however, that it was some African territory far away to the south of Egypt from which negro people came. Professor Maspero tells us that "all that lay beyond Punt was held to be a fabulous region, a kind of intermediate boundary land between the world of men and that of the gods, the 'Island of the Double,' 'Land of the Shades,' where the living came into contact with the souls of the departed." Following the accounts given by Schiaparelli, Erman, and himself, Professor Maspero continues the story in the following most significant sentences: "It [the "Land of the Shades" beyond Punt] was inhabited by the Dangas, tribes of half-savage dwarfs, whose grotesque faces and wild gestures reminded the Egyptians of the god Bes. The chances of war or trade brought some of them from time to time to Punt or among the Amamiu [the people around Wady Halfa]; the merchant who succeeded in acquiring and bringing them to Egypt had his fortune made. Pharaoh (King Assi of the fifth dynasty—about 3300 B.C.) valued the Dangas highly, and was anxious to have some of them at any price among the dwarfs with whom he loved to be surrounded; none knew better than they the dance of the god—that to which Bes gave way in his merry moments. Towards the end of his reign Assi procured one which a certain Biurdidi had purchased in Punt. Was this the first that made his appearance at court, or had others preceded him in the good graces of the Pharaohs? His wildness and activity, and the extraordinary positions which he assumed, made a lively impression on the courtiers at the time and nearly a century later there were still reminiscences of him."[7] 70 years after King Assi "an officer, Heru-Khuf, was sent by Pepi II. (sixth dynasty) to bring back a pygmy alive and in good health from the land of great trees away to the south." "That the Danga came from the South we know from a later inscription at Karnak, and that the word meant dwarf is clear from the accompanying determinative of a short person of stunted growth."[8]

The whole of this account seems to me to be a perfectly straightforward and indubitable reference to the pygmies. But Professor Maspero says the determinative used shows that a *dwarf* and not a *pygmy* is referred to in this account. But we cannot have "a race of dwarfs" because a race of small people can only be pygmies and if the determinative used in this connexion is that of a distorted body this is conclusive proof of the suggestion, which I have already made above, that the same determinative is applied equally to the subjects of partial and complete nanism as well as to pygmies. Then, again, if this Danga was so highly estimated and "placed among the dwarfs" and remembered for nearly a century afterwards, he could not have been an ordinary dwarf; nor is there any obvious reason why they should have specially sent a long distance to the southern land to obtain a mere dwarf. Dwarfs are so common in every population, and certainly not less so in Egypt,[9] that one cannot believe all of these remarks can have been applied to any kind of dwarf but must refer to a pygmy. Professor Maspero offers the further objection that the time which it took—two months by water—to reach Egypt from the Danga's country (beyond the land of Punt) is not nearly sufficient to cover a journey from the present habitat of the pygmies to Egypt. It is not easy to estimate how far this would remove the pygmy country from Egypt. That it was a long way off is probable from the rarity of Dangas in Egypt and the fact that the Dangas obtained in the fifth and sixth dynasties were only stray individuals who had reached the land of Punt or the country of the Amamiu. Then, again, we must not forget the probability that the territory occupied by the pygmies extended much further north in those times than now. I suppose that no one now has any doubt of the essential accuracy of the very detailed and circumstantial account of the pygmies and the geographical features of their country given by Herodotus in the oft-quoted description of the voyages of the adventurous Nasamonians in search of the source of the Nile.[10] My friend, Mr. J. I. Craig, of the Egyptian Survey Department, tells me that the only river which corresponds to the description given by the Nasamonians is the Sobat. If this is so and the habitat of the pygmies reached as far as the Sobat in the third century B.C. one is quite prepared to learn that it extended much farther north in the remote time of the sixth Egyptian dynasty. These speculations are, however, quite futile if we refuse to admit that the very definite and precise reference to the Dangas in Schiaparelli's work is an account of the real pygmies. In the Greek and Roman classical writings there are numerous references to the pygmies, which in the works of Herodotus and Aristotle become so definite and exact that there can be no doubt as to their meaning.

The Englishman Andrew Battel, of Leigh in Essex, described the pygmies which he saw in Angola at the end of the sixteenth century as "little people called *Matimbas*, which are no bigger than Boyes of twelve years and very thicke"; and nearly a century later the Dutch geographer Dapper published the first account of the Akka pygmies under the name Bakke Bakke from reports which he had received from a fellow-countryman trading on the Guinea Coast. These accounts met with little credence at the time and at the beginning of the nineteenth century these stories with those of the classical writers were relegated to the domain of fairy tales. With the growth of a fuller knowledge of natural history and of a more critical inquiry into the facts of nature and the records of history all of these reports were "explained away" as mere travellers' tales or as highly coloured accounts of tribes of apes and monkeys. But from the middle of the nineteenth century onwards numerous travellers in various parts of Equatorial Africa and its neighbourhood began once more to record reports which they had heard of diminutive races of men. Dr. Touchard (1861) and Admiral Fleuriot de Langle (1868) described the rapid extinction of a pygmy race in the Gaboon region. M. Paul du Chaillu (1867) in penetrating the forest behind the French possessions in West Africa came upon a pygmy race in Ashongoland between the Gaboon and Congo rivers. Speke and, at a later period, Stanley (1876) heard of the Batwa or Watwa pygmies along the upper waters of the Congo, whom Lieutenant Wissmann and Dr. Wolff met and described in 1887.

[9] During the few weeks of the pygmies' stay in Cairo I saw three fully grown dwarfs all much smaller than these pygmies.

[10] See Flower, op. cit., quotation from Herodotus, Book II., 32, Rawlinson's translation, p. 47.

The Akka dwarfs seen by Dapper were rediscovered by Professor Schweinfurth two centuries later (1870) and have been seen by the Italian geographer Miani, by Emin Pasha and Stanley, by Stuhlmann and several others. Several of these people have been studied both in Africa and in Europe, and the skeletons of two of them, sent to England by Emin Pasha, have been fully described by the late Sir William Flower. The late Sir Henry Stanley, and more recently Sir Harry Johnston and Dr. David have seen the Mbute (Bambute, Wambutti) pygmies. They are said to live in a territory further west, near the Uganda frontier; but it is very doubtful whether there is any distinction between the Akkas and the Mbute. Stuhlmann says that among the neighbouring tribes the name Akka is often applied to the Mbute. When I questioned the chief of Colonel Harrison's party as to the name of his people he called them "(M)Akkaba." It is highly probable that the names Mbute, Akka, and Batwa are little more than geographical terms without any ethnological significance. In his work on the "Uganda Protectorate" Sir Harry Johnston gives a very full account of the pygmies and describes a more widely scattered negroid population composed of small people scattered amongst the larger negroes. These he calls the "pygmy-prognathous" group and regards as distinct from the true pygmies, although Dr. Shrubsall, who has written a report on Johnston's anthropological data, considers that they exhibit signs of affinity with the pygmies. As Sir Harry Johnston describes the unions which take place between men of neighbouring tribes and pygmy women it is perhaps not surprising to find a scattered population of small negroids beyond the pygmy domain.

The age of the individuals.—In discussing the size and relative proportions of the body in pygmy people the question of the age of the individuals studied is of the utmost importance, for all our conclusions may be vitiated if we treat the mensurations of children as those of adults. It is therefore desirable to study the problem of the determination of the ages with the utmost care. As the people themselves have no ideas whatsoever of their age and the statements made concerning them are obviously mere guesswork of the crudest description,[11] we can at the outset put aside all preconceived ideas as to their ages and study the question on the evidence afforded by the state of their teeth and bones. The value of the evidence afforded by the teeth is not so great as that of the osseous tissues, because the dates of eruption of the former are liable to great variation. There is no doubt that there is a definite tendency amongst the African people for the teeth to cut the gums at an earlier period than in Europeans. It is difficult to obtain definite information in support of this contention because so few people in Egypt and the neighbouring countries have any idea of their exact ages or of those of their relatives. It is a common occurrence for the third molar teeth in Egyptians to cut the gums before the eighteenth year and cases in which these teeth had erupted as early as the fourteenth (and even the thirteenth, according to Dr. Harold Nolan) year have been met with. With reference to the second molar teeth I am unable to make any statement as to the date of eruption from my own knowledge, but my friend, Dr. Nolan, who has had occasion frequently to examine the teeth for medico-legal purposes, has the idea that these also (and, in fact, all the teeth) are precocious, judged by the European standard. The difficulty of ascertaining the exact age in all except the rarest cases has so far rendered it impossible to make any more definite statement regarding this important subject.

The party of pygmies with whom we are at present concerned consists of six individuals, four of whom are males and two females. Of the men only one—the chief, Bohani (or Morgany)—had cut his wisdom teeth and that had happened many years ago. He had lost many of his front teeth: his third molars had the same form and were almost as large as the other molars. He had a long oval palate and the teeth were big. The youth Mafutiminga had not yet cut his third molar teeth. His molars were bigger than those of the others. There was a large gap, 6·5 millimetres, between the two median incisors placed chiefly on the left side of the mesial plane. Judged by the Egyptian standard there is the possibility that a youth who had not cut his third molar teeth may not yet be 18 years of age, if as much. The third male, named Matuha, had not yet cut any of his wisdom teeth and the boy Mongungu had not only not cut his wisdom teeth but the crowns of the second molars were elaborately sculptured and obviously new as though recently erupted and the gums around these teeth were still red from the irritation caused by the tooth breaking through. In Europeans this is supposed to take place in the twelfth year. There was a distinct hiatus between the canine and second incisor teeth, which probably indicated that the canine had not yet been pushed up to its full height. In other words, the canine which cuts the gum during the eleventh year in Europeans had not yet finished growing—i.e., had only recently erupted in this boy. So that even judged by the European standards the evidence of this boy's teeth points to the fact that he is no more than 12, or perhaps even 11, years of age. Of the two females, one—Amooriape—is an old woman with a complete set of well-worn teeth; in fact, judged by her teeth she is much the oldest of the party and may be 40 or 50 years of age. The other woman—Kuarhe—also has a complete set of teeth, but her third molars appeared to have only recently erupted. With the object of throwing further light upon the problem of the determination of their ages Dr. Khayatt made skiagrams of the hands and wrists of the whole party and of the elbow in the cases of Matuha and Mongungu. It had been our intention during the last few days of the pygmies' stay in Cairo to submit all parts of the skeletons (of all of them) to examination by the Roentgen rays, but the interruptions caused by their treatment for ankylostomiasis and their sudden departure two days before it was expected interfered with this plan. At the same time, we have been able to obtain sufficient data to enable us to estimate their age by European standards. In the cases of the man Bohani and the old woman Amooriape the bones of the hand and wrist were perfectly ossified, but in the other four individuals the skeleton exhibited various stages of immaturity.

I shall begin with the consideration of the youngest of the party, Mongungu. Skiagrams show that the proximal extremities of all the phalanges of both hands are still widely separated from the shafts. The proximal end of the metacarpal of the thumb is separated from the shaft by a gap of a similar extent to that of the phalanges. In this respect it presents a marked contrast to the epiphyses for the heads of the other four metacarpals, the line of separation of these from their shafts being hardly visible in the right hand and not at all—if we ignore some doubtful traces of the epiphyseal line in the second and third metacarpals—in the left hand. If these epiphyses have really joined their shafts—there is, of course, the possibility that a slight obliquity of the bones may have caused the narrow epiphyseal gap to be hidden—it is a most extraordinarily precocious development; but it cannot be distinctive of all pygmies (at any rate, the date of union cannot be so very early) because in the much older boy Matuha the epiphyseal gaps in the metacarpals are distinct in the left hand although they are almost closed in the second, third, and fourth metacarpals of the right hand. In Matuha's right hand the epiphysis of the fifth metacarpal seems to be perfectly fused to its shaft, although the epiphyseal gap is quite open in the corresponding finger of the left hand. All of the phalangeal and metacarpal bones in Mongungu's hands still retain their infantile shapes and in this respect present a marked contrast to all the other members of the party. The bones of the carpus have not yet attained their perfect forms and their density is much less than the carpalia of the other pygmies. The pisiform is represented by a shadow four millimetres in diameter, the edges of which are ill-defined, whereas the corresponding diameter in the man Bohani is 11 millimetres and its edges are sharply defined. This bone is obviously in a process of ossification in Mongungu and according to Debierre (quoted by Professor Arthur Thomson in Cunningham's "Textbook of Anatomy," p. 203) this takes place approximately in Europeans between from 10 to 12 years of age. Both epiphyses of the radius and the lower epiphysis of the ulna are widely separated from their respective diaphyses. I am unable to determine whether the epiphysis for the olecranon process is present. The most interesting feature in the lower end of the humerus is the presence of the small separate nodule representing the external condyle, which in Europeans develops and fuses with the capitellum in the twelfth year. The internal epicondylar and the capitellar epiphyses are separate but it is not certain whether the trochlear centre is present. All the evidence of the humeral epiphyses, of the state of the pisiform, of the infantile forms of the bones of the hand, and of the state of the teeth indicate Mongungu's age as being 12 years if we adopt the European standard of tooth and bone development. If the pygmy standard is different it is in the highest degree probable that a race which is certainly more primitive than the European and is composed of individuals of small stature will come to maturity at a period of life which is certainly not later; and it is quite possible or even probable that they may mature at an earlier age. In other words, the maximum limit of Mongungu's age is 12 years and there is always the possibility that he may be considerably less. His whole appearance agrees with this estimate. His genital organs are still infantile. He has not yet developed any pubic or axillary hair. Nor does he exhibit that shame in exposing his naked body which is apparently so acutely felt by the other members of the party.

---

[11] A boy of the party who had not reached the state of puberty and whose gums were still red from the irritation caused by the eruption of the second upper molar teeth was said to be 18 years of age.

Like Mongungu, neither Matuha nor Mafutiminga has been circumcised, Bohani (the only bearded member of the party) being the only one circumcised. Sir Harry Johnston has made the statement that "the males of all the Congo pigmies seen by [him] were *circumcised*."[12] This is clearly not a universal rule among the people; but it is curious that the only one of this party to be circumcised should also be the only one whose bones have reached a state of maturity. This naturally suggests that circumcision may possibly be done as part of the initiation into manhood. But both Matuha and Mafutiminga have reached the age of puberty, as the state of their genital organs and the growth of pubic and axillary hair show; and the latter is said to be the husband of the woman Kuarhe. So that there is nothing to show that the rite of circumcision has any definite significance among these people. The most important piece of evidence as to the age of Matuha is afforded by the internal epicondyle of the humerus, which is still separate. In Cunningham's "Text-book of Anatomy" Professor Arthur Thomson says in one place that this epiphysis fuses with the shaft at 17 or 18 years and elsewhere on the same page (189) he puts it at 18 or 19 years; in Quain's "Anatomy" Professor Thane puts it at 18 years. This would apparently make 18 years as the age limit of Matuha. On the other hand, the head of the radius seems to be perfectly fused to the shaft. Professor Macalister in his text-book (p. 149) says that this takes place at 16 years, Professor Thane puts it at 17 or 18 years, and Professor Thomson allows from 18 to 20 years. According to these estimates Matuha is at least 16 years but may be as much as 20 years of age but the state of the humerus cuts one or two years off the latter estimate. The lower epiphyses of the ulna and radius are, of course, still separate. The proximal epiphyses of the first and second phalanges are still separate, while those of the ungual phalanges appear to be in the act of fusion. These epiphyses may join at any time between 18 or 20 years.

The conclusion to be drawn from these figures is that Matuha (if judged by European standards) would certainly be more than 16 years of age and less than 18 (adopting Thane's figures) or at most 19 years (if we accept Thomson's dates). The probability is that he is not more than 17 or at most 18 years, an inference which is possibly supported by the absence of the third molar teeth. If this is so the ossification of the metacarpus is unusually precocious, though not nearly to such an extent as Mongungu's.

In the case of Mafutiminga, whose third molar teeth have not yet erupted, I have only the evidence of the hand and wrist to go on. The lower ends of the radius and ulna are in the same condition as Matuha's—i.e., the epiphyses are separated from the shafts; the proximal ends of the first and second phalanges are still unjoined, whereas the third phalanges seem to be completely ossified. The epiphyseal line is still visible at the base of the metacarpal of the thumb but whether it is present or absent at the distal ends of the other four metacarpals is doubtful. All of this evidence so closely coincides with that relating to Matuha that any conclusion drawn from the data at my disposal in the case of one must also apply to the other.

In the case of the young woman Kuarhe the hands seem to be fully ossified but the lower epiphyses of the radius and ulna are still separate. Very different estimates of the age at which union takes place in these bones have been given by various writers; the fusion in the case of the radius is said to take place at 19 years (Macalister), about 20 years (Thane), or from 20 to 25 years (Thomson), and in the case of the ulna at 20 years (Thane and Macalister) or 20 to 23 years (Thomson). If we accept Macalister's figures this young woman, even when judged by European standards, is not more than 19 years but according to the estimates given by Thomson there is a bare possibility of her age being as much as 23 years. At the same time there are grounds for the belief that females reach maturity at an earlier age than males, an additional reason for adopting the lower estimate in this case.

We have no standards by which to estimate the ages of the man Bohani and the woman Amooriape. The former looks like a man in the prime of life and might be any age between 30 and 40 years. The woman looks much older than the man and yet she does not exhibit any pronounced signs of senility. Although both the women spent the greater part of a month in Cairo the matron of the Kasr-el-Aini Hospital tells me that neither of them menstruated during that period.

Name.	Sex.	Height.	Weight.
Bohani	M.	1·367 metres.	7 st.
Mafutiminga	M.	1·378 ,,	7 st.
Matuha...	M.	1·311 ,,	4 st. 11 lb.
Mongungu	M.	1·158 ,,	3 st. 7½ lb.
Amooriape	F.	1·286 ,,	3 st. 11¾ lb.
Kuarhe...	F.	1·334 ,,	5 st. 6½ lb.

The average height of 38 Akka pygmies from the Monbuttu country is given as 1·378 metres by Deniker[13]: a series of 30 Akkas measured by Emin Pasha yielded an average height of 1·36 and a series of 98 Watwa pygmies measured by Dr. Wolff gave an average of 1·42 metres.[14] The average height of six male Mbute pygmies measured by Sir Harry Johnston[15] was 1·452 metres and the two women measured yielded the figures 1·292 metres and 1·427 metres. From these figures it will be seen that the two fully grown pygmies in Colonel Harrison's party are small even for pygmies. In fact, the young woman Kuarhe and the young man Mafutiminga are taller than the adult representatives of their respective sexes, although there is still a possibility that they may have not yet finished adding to their stature.[16] In Europeans the average weight in males is doubled between the ages of 12 and 24 and onwards,[17] so that the estimate of 12 years as Mongongu's age and his weight and that of Bohani tally with these figures.

The average weight of a European youth at 18 or 19 years is almost that of a fully grown man. This quite supports the estimate of Mafutiminga's age, although he is a very heavily built, clumsy youth who, when fully grown, will probably be much bigger and heavier than Bohani. The size and weight of Matuha suggest that he is not nearly fully grown and incline to the view that even 18 years is an exaggerated estimate of his age. The average weight of a boy of only 17 years is considerably greater than that of a fully grown woman. Yet the young woman Kuarhe is nine and a half pounds heavier than Matuha.

The size of the limbs.—The illustrations appended to this account give a good idea of the proportions of the limbs. A study of the measurements of living individuals made by various investigators shows that a considerable proportion of the figures, even when compiled by trained observers, are quite untrustworthy as an index of the size of the bones. In no other way is it possible to explain the great discrepancies which are found in the recorded sizes of the limbs of living pygmies. In addition to the measurements made on numbers of living pygmies by various travellers we have the exact measurements of the skeletons of two Akkas by the late Sir William Flower[18] and Dr. Frank Shrubsall.[19] In a female Akka pygmy 1·218 metres in height the humerus was 19·8 per cent., the radius 15·7 per cent., the femur 27·5 per cent., and the tibia 22·3 per cent. of the total stature. The most noteworthy feature of these measurements is the great proportionate length of the forearm which is more than 1 per cent. greater than that of Europeans; in this respect the pygmies are distinctly negroid. The other measurements (those of the femur, tibia, and humerus) are almost identical with the average proportions given by Topinard for tall Frenchmen.

In the six pygmies of Colonel Harrison's party the radius is proportionally shorter in the women than in the men, being only 15·2 per cent. in Kuarhe and 15·3 per cent. in Amooriape; in the man Bohani and the boy Mongongu it is 15·6 per cent., in Matuha it is 15·7 per cent., and in Mafutiminga it rises to 16·5 per cent. of the total height. The relatively enormous size of the arm and forearm in the latter youth is well demonstrated in the illustrations. The divergences of the proportions of the other long bones in these six individuals to their body-heights are all within the range of variation given by Topinard for Europeans. There is a noteworthy variety in the size of the feet, as the photographs clearly show. Whereas the feet of the two women (both 195 millimetres long), the boy Mongungu (194 millimetres) and the man Bohani (198 millimetres) are quite proportionate to the body-height, those of Matuha (220 millimetres) and Mafutiminga (235 millimetres) are large and unshapely. Many statements have been made by previous writers in reference to the separation of the great toe from the other four toes and the power of grasping with these toes. Although these statements are true of these pygmies the separation of the toes is no greater than that of many negroes and the power of grasping is equally well developed in other people, even European children, who habitually go barefooted. The limb bones of the two pygmy women dissected in Cairo are all extremely slender—quite disproportionately so, when compared with their length. Most of the characters of the scapula and pelvis agree with those described by Flower and Shrubsall in the case of their pygmies but the pelvis in my cases was not so markedly dolichopelvic as in Flower's case.

The head.—So far as the form of the head is concerned these six people form a remarkably uniform group. All the heads are ovoid in norma verticalis and the length-breadth indices are respectively: 76·5 (Mongungu), 77·7 (Bohani), 78 (Mafutiminga), 78·7 (Amooriape ♀), and 79·1 in both Matuha ♂ and Kuarhe ♀. The heights of four of the crania (measured with Pearson's spanner) are almost identical (135, 137, 139, 139); the two old people have much the loftiest heads, the woman Amooriape's height being 144 millimetres (head length 174) and the man Bohani's cranial height being 155 millimetres (head length 184). The horizontal circumferences of the heads, taking the names in the same order as in the list of cephalic indices, are 514, 544, 533, 518, 514, and 505 millimetres respectively. As a measure of their prognathism the indices expressive of the proportionate lengths of the nasal and prosthionic radii are 111, 104, 115, 110·5, 107, and 108. Bohani is the least prognathous and Mafutiminga the most.

Much stress has been laid by previous writers on the comparative shortness of the crania of pygmies in comparison with their larger negro relatives and the Bushmen population of South Africa. These six individuals exhibit this feature in its characteristic form. The figures quoted above show that the degree of prognathism is a very variable quantity in these people; it is considered to be one of the chief distinctive features of pygmies in contact with Bushmen. The cranium of one of the two pygmies dissected in Cairo is quite orthognathous and even when due allowance is made for the atrophy of the alveolar process, which has followed the loss of the incisor teeth, it does not approach the average condition of pygmy prognathism. When a character exhibits such extreme variability it loses much of its value as a distinctive feature.

In individuals such as these pygmies, in whom the root of the nose is exceptionally flattened and very broad, it is not easy to measure the length of the nose with any degree of accuracy. The nose is exceptionally broad in the four males (varying from 40 millimetres in the boy Mongungu to 49·5 millimetres in Mafutiminga) but is considerably narrower in the women (34 millimetres and 39 millimetres respectively). The characteristic pygmy type of nose is seen in most distinctive form in Matuha and Bohani—the root is broad and very flat, the tip broad and flattened, and the alæ greatly expanded so as almost to equal the tip of the nose in size. The illustrations render any attempt at a detailed description unnecessary. Mongungu's nose represents a youthful phase of the same type. Although actually broader than that of any of the others, Mafutiminga's nose conforms rather to the common negro type, the disproportion between the sizes of the central part and the alæ being much more marked than it is in the other males. The nose of the old woman Amooriape has the characteristic pygmy form but is considerably narrower than that of the men. The root of her nose is so flattened that the broad space between her eyes is almost level. The younger woman Kuarhe's nose exhibits none of the pygmy or even negro form and resembles rather the nasal types so common in Abyssinia and the neighbouring regions, where there is a mixture of Hamitic, Semitic, and negro populations. In profile, however, the flattening of the tip of her nose produces a greater resemblance to that of the old woman than in norma verticalis.

The lips also are quite characteristic. Instead of the massive, fleshy, everted lips of the negro the pygmy has long thin lips the upper of which has a noteworthy subnasal projection. This form of lip with the flattened nose above it gives a strikingly Simian appearance to the features, especially during such acts as drinking and speaking. This is seen to best advantage in the old woman when she is just about to drink: her lips are then pouted out in a tubular manner just like those of a chimpanzee. The lips of the younger woman have been perforated in three places. The ears of all are small; the lobules are poorly developed, especially in the ears of Matuha and Mafutiminga, and in the former the pinna is rather crudely formed. Mongungu's lobules are not perforated but one or both are pierced in the others. The mandible is very narrow and pointed and the chin small in all. Bohani alone has a beard; it consists of a small stubbly growth of short closely rolled hair on the chin and upper lip. The pubic and axillary hair in the two women and the two youths presents similar characters. Bohani has similar hair on his chest and abdomen.

Much has been written by Emin Pasha, Yunker, Stanley, Stuhlmann, and Johnston, among others, of the down-like hairy covering of the whole body of the pygmy people. Such hair is certainly present in these individuals, but I doubt whether, with the possible exception of Mongungu, this hair is developed to any greater extent than in many Europeans. In Mongungu it is distinctly well developed, especially on the back. It is perhaps noteworthy that he is much the youngest of the party. The hair of the head consists in all six of the characteristic discrete "pepper-corn" balls, closely rolled, and of a peculiar dull lustreless appearance, not exactly black but of an indefinite greenish-grey tint. In the youth Matuha the hair was very short on the right side of his head but more abundant on the left side. He had probably at some quite recent period had the right side of his head shaved. In Dr. David's photograph of a group of Mbute pygmies which was given me by Professor Schweinfurth (and has been published, so he tells me, in a reduced form in "Globus") various fantastic methods of dealing with the hair are shown. One woman has the hair removed from the right side and another from the left side of her head; another woman and two men have had the whole of their hair removed except a frontal fringe; several of both sexes have had symmmetrical similar areas denuded of hair on both sides and several men have had their foreheads shaved so as to convert the edge of the hairy-covering into a sharply defined line. Matuha has apparently been subjected to this procedure.

Other features.—A noteworthy peculiarity of all pygmies, both old and young, is the extraordinary prominence of the abdomen. That this is not the result of overfeeding since they have become exiles is shown by the fact that this feature is equally pronounced in those individuals who have been photographed in their native forests (as in Dr. David's photograph). In one of the pygmy women dissected by me this prominence of the paunch was associated with a peculiarity of the colon. The cæcum was placed high up in the lumbar region and from it the colon bent downward into the right iliac fossa; then becoming enormously distended it pursued a sigmoid course across the abdomen, completely filling the anterior part of the cavity and occupying the abdominal bulging. The splenic flexure was separated from the spleen by the pancreas. Practically the whole of the colon was thus constituted by the large stomach-like organ which would by most writers be labelled transverse colon.

---

[18] Op. cit., supra.

[19] Op. cit.

Until Stuhlmann exhibited photographs showing definite steatopygia in a pygmy woman it was commonly supposed that this condition never occurred in this race and its absence was regarded as one of the great distinguishing features when the pygmy was compared with the Bushman. In one of the women of Colonel Harrison's party—Kuarhe—there is a very steatopygous condition, whereas in the old emaciated woman there is not only no trace of it but the buttocks are unusually small.

In the pygmy women dissected in the Cairo School of Medicine the facial muscles presented the usual negroid features—an exceptionally reddish colour and a much greater diffuseness than is found in the ordinary European. In one of them a pair of symmetrical sternales muscles were found, their upper tendons being attached in front of the manubrium sterni and the lower tendons in front of the seventh costal cartilages. In the same subject the trapezius muscle gave off a slip to the sterno-mastoid on the left side; neither omo-hyoid muscle had an intermediate tendon but merely an ill-defined tendinous intersection. The brain of this woman, after having been in the body preserved by intravascular injections of 10 per cent. formol for three days, weighed 880 grammes. So that when it was fresh it probably weighed about 850 grammes. But as it had a softening of the motor speech centre in the left hemisphere and a second softening in the parietal area of the right hemisphere its weight in the healthy state may have been nearer 900 grammes. That the brain had shrunk (as the result of old age) was shown by the great enlargement of the frontal air cells as the consequence of the marked inner bulging of the internal table of the frontal bone. The brain of the younger second pygmy woman (the lower femoral epiphysis of whom was still separate) weighed 950 grammes after formalin. The average brain weight of 100 fellahin women weighed by me was 1190 grammes. In European women it is about 100 grammes heavier and in Soudanese women almost as much lighter. Taking into consideration the size of these women a brain weight of 900 grammes compares not unfavourably with that of Soudanese women of bigger stature. At the same time such a small figure for a human being has a considerable significance when it is recalled that it is so little bigger than the brain of pithecanthropus as estimated by Dubois. Perhaps more surprising than the small size is the fact that these brains exhibit no more simian likeness than, if as much as, most negro brains. Symmetrical lunate sulci (Affenspalten) of a moderately large size were present in the younger woman but in the other brain they were very small and not at all pithecoid. The Sylvian fossa was widely open and a large part of the insula was exposed, but this often occurs also in Soudanese and other brains. The characters of the skull of the old woman show a considerable resemblance to those of the Akka woman's skull described by Flower. The nasal bones were fused as in the apes. The spheno-maxillary fissure was widely open. The tip of the great wing of the sphenoid just reached the parietal bone. The temporo-maxillary joints were completely disorganised by severe rheumatoid arthritis.

The abundant secretion from the large sebaceous glands yielded a most powerful and objectionable odour which did not become appreciably less until more than a week of daily ablutions and even up till the last day of their stay in Cairo the odour still clung to them. It may be compared to the well-known "nigger smell" but it was even more pronounced.

These pygmies show a strange indifference to what is going on around them. They seem to be altogether devoid of ordinary curiosity. Even the loud buzzing of a Ruhmkorff coil and the illumination of a Crookes's tube were not sufficient to attract their attention to either. Their sense of modesty was most pronounced, especially when it is recalled that they are said to go naked in their own country. They are extremely shy and reticent until they become familiar with the people around them. Their music differs entirely from the Egyptian and Arabic tunes but is indistinguishable from those of the Soudanese negroes. Unlike the native inhabitants of Egypt they are able to recognise photographs and pictures that are shown them.

Conclusion.—As the late Sir William Flower and many other writers have repeatedly stated, the pygmies are certainly negroid and many of the negro features, such as the projection of the jaws and lips, the flatness of the nose, the elongation of the palate, the large size of the teeth, and the characters of the hair, are even exaggerated—i.e., are ultra-negroid in the pygmies. From the time the pygmies were re-discovered in recent times there have always been writers who have put forward the many points of resemblance between the pygmy and the Bushman—the smallness of stature, the "pepper-corn" hair, the flat, broad nose, the convexity of the subnasal space, and the occasional steatopygia—as arguments in favour of the recognition of a racial affinity, and it must be confessed that this array of resemblances is difficult to "explain away." Deniker has examined all these points of resemblance in some detail and has come to the conclusion that none of them will stand close examination.[20] Shrubsall, on the other hand, as the result of a comparison of the crania of Bushmen and Flower's Akka pygmies, expressed the opinion that "it seems probable that the Negrilloes and the Bushmen are allied." He goes on to state that "the principal objection to such a view is that the phenomenon of steatopygia has as yet not been described among the Negrillo races."[21] This was written, of course, before Stuhlmann showed that this condition does sometimes exist in pygmies. These early comparisons of pygmies with Bushmen probably led observers to exaggerate the lightness of the skin tint of the former. That the pygmies are lighter in colour than many negroes is obvious at a glance, but it cannot be too strongly insisted on that many true negroes have the same chocolate-brown coloured skin as the pygmies. Even this small party of six exhibit a wide range of colour. Mafutiminga, in colour as in many other features, is a dusky negro, whereas the old woman Amooriape is of a comparatively light brown tint and the colours of the other four are intermediate between these two extremes.

If we attempt to sum up the features of these pygmy people we have no reason for regarding them as either more simian or more primitive in structure than ordinary negroes. In comparison with the Bushman they must be considered as much more decidedly negroid. When we take into consideration the many undoubted resemblances of pygmies and Bushmen it is easier to picture these likenesses and their attendant differences as the results of a diverse specialisation of two branches of one stock rather than as the product of a tendency to convergence of two independent races. So far as we know the structure of the pygmy people there is no reason for regarding them as other than merely small negroes. The variability of type exhibited in even this small party probably indicates that the pygmy peoples have considerably intermingled with other races.

NOTE ON INTESTINAL WORMS FOUND IN AFRICAN PYGMIES,

BY DR. A. LOOSS.

I avail myself of the opportunity afforded by the publication of Dr. Elliot Smith's article on African pygmies to make a few provisional remarks on the intestinal parasites found in the six Mbute (Bambute or Wambitti) pygmies described by him. Very little being as yet known of the parasites of man in Central Africa, Dr. H. P. Keatinge suggested that I should examine the stools of the six individuals. When this was done it was found that all of them harboured the eggs of worms. There were altogether five species represented: an ankylostoma, an ascaris, a trichocephalus, schistosoma hæmatobium, and oxyuris vermicularis. The first four genera in this list were recognisable by the presence of their ova in the dejecta and the last named was found later in the shape of some full-grown specimens. The ankylostoma eggs were discovered in all six individuals, two of whom presented them in fairly considerable numbers. The trichocephalus was found in two of the men, the ascaris in one man and one woman. Schistosoma and oxyuris were each found in one male person only. The smallest boy (Mongungu, aged 12 years) harboured all species except oxyuris. The schistosoma eggs were found in this fæces only; they were lateral-spined and rather scanty. In some specimens of urine (very small in amount) none could be discovered.[22]

---

[20] The Races of Man, p. 455.

[21] Journal of the Anthropological Institute, 1897, p. 283.

In size, shape, and structure of their contents the schistosoma eggs fully agreed with the ova of the Egyptian bilharzia; thus I have no doubt that they really belong to this species. As to the other kinds of eggs observed in the fæces of the pygmies, I was not so sure of their identity. There was naturally no doubt as to the genera of the parent worms, but all the eggs in their general appearance slightly differed from those of the well-known species infesting man elsewhere. The ascaris eggs, varying between 0·059 to 0·042 millimetre and 0·063 to 0·05 millimetre, and thus coinciding in size with the eggs of ascaris lumbricoides, differed from these by their paler and decidedly less refractive shell. The albuminous envelope raised in the characteristic tubercles was very thin and often quite absent. The protoplasm of the undivided egg-cell seemed to be markedly less granular than in the eggs of ascaris lumbricoides, the entire eggs becoming thus paler than usual. The trichocephalus eggs did not quite reach the size of those of trichocephalus trichiurus. In Egyptian specimens of this species I find the length of the eggs to vary between 0·063 and 0·067 millimetre and the breadth between 0·03 and 0·034 millimetre, whereas the eggs in the stools of the pygmies almost uniformly showed a length of 0·054 and a breadth of 0·025 millimetre. Moreover, their shell which, in trichocephalus trichiurus, is of relatively considerable thickness with strongly refractive outlines, was in the eggs yielded by the pygmies only about half as thick, the polar plugs but feebly developed and less refractive too. The ankylostoma eggs, finally, presented a striking difference of another kind. It is a well-known fact that the eggs of ankylostoma duodenale in fæces immediately after evacuation show the original egg-cell divided into four embryonic cells, eggs with fewer or more cells forming the exception to the rule. In the fæces of the pygmies, even when examined a quarter of an hour after evacuation, the great majority of the ankylostoma eggs exhibited an embryonic body composed of from eight to 16 cells, eggs with four cells being present also but by no means so frequently as in the case of ankylostoma duodenale. Measurements of a number of these eggs showed that, on an average, they also possessed slightly larger dimensions. Apart from some exceptional cases the eggs of ankylostoma duodenale vary in length between 0·056 and 0·061 millimetre and in breadth between 0·034 and 0·038 millimetre. The corresponding figures found on the eggs in the stools of the pigmies were 0·059 to 0·065 millimetre and 0·038 to 0·04 millimetre.

Owing to these peculiarities observed in the eggs it seemed worth while to try to obtain the full-grown worms. At my request Dr. Keatinge kindly agreed that the six people should undergo an anthelmintic treatment in the Kasr-el-Aini Hospital. A first "cure" was made with thymol in the usual way adopted in the hospital, but owing to the small size of the patients only four grammes of thymol were given. The result was almost negative, only two ankylostoma worms being expelled from the six people. Since it did not seem advisable to increase the dose I suggested that the "cure" should be repeated with the "white mixture" recently recommended for ankylostoma duodenale as both efficacious and harmless by Dr. Herman in Mons, Belgium. The mixture is composed of eucalyptus oil, 2 grammes; chloroform, 3 grammes; and castor oil, 40 grammes. The result was, so far as the ankylostoma worms were concerned, very satisfactory. The "cure" produced altogether about 150 worms and a repetition made after three days' interval about 30 worms more. All were still living when voided and thus furnished excellent specimens for anatomical research. Of the other species, the eggs of which had been found in the fæces, only one female trichocephalus was voided in addition to the few oxyurides mentioned above. Owing to this result I am as yet not able to tell whether the differences observed in the ova have their cause in specific differences of the parent worms or whether they represent mere local aberrations.

A close examination of the ankylostoma specimens obtained by the treatment revealed them to belong to the species necator Americanus, the "New World hookworm," which was some years ago recognised by Stiles as a distinct species widely spread, in addition to the true ankylostoma duodenale, among the white and coloured population of the southern parts of the United States. The same species is also very common in South America and represents the "ankylostoma duodenale" mentioned by earlier South American, especially Brazilian, writers. I have made a careful comparison of North and South American specimens of the species with the specimens voided by the pygmies but have not been able to find any specific differences.

It may thus be considered as settled that the "New World hookworm," necator Americanus (Stiles), occurs also in natives of Central Africa. This fact is not without a certain interest from the point of view of the geographical distribution of the species. It is said that the pygmy people live scattered thoughout the forests of the tropical belt of the African continent. The more or less frequent occurrence of "ankylostoma duodenale" has been reported from the eastern as well as from the western coast of Africa (Zanzibar, Uganda, German East Africa, Congo to Senegambia). Now there seems to be no just reason to assume that the necator should be restricted to the pygmies; it is, on the contrary, much more probable that its geographical range comprises the whole native population of the tropical belt of Africa—naturally, so far as the hydrographic conditions of the land allow of the propagation of the worm. If this be true—and I am almost convinced that it is—then it would follow that what, in the reports alluded to above, was considered as ankylostoma duodenale is in reality necator Americanus; if not exclusively, at least to some extent. So far as I can gather from the literature at my disposal in none of the respective cases has a minute examination of the anatomy of the parasite been made, its presence was only stated from the appearance of the ova in the fæces, or after finding the full-grown worms in post-mortem examinations. Since both eggs and parent worms of the two species resemble each other very closely on superficial examination—indeed, their definite distinction by Stiles dates back only three years ago—such a confusion is almost a matter of course. Since I propose to return to the fuller discussion of this subject on another occasion I abstain from entering into further details in this place. The principal object of this note is to state the occurrence of the "New World hookworm" in natives of Central Africa and to attract the attention to its probable occurrence in other parts, especially the coasts of tropical Africa. For physicians practising in these countries it would be an easy matter to settle the question, either by themselves determining the species of the parasite or by sending some well-preserved material for identification to experts. I myself would gladly undertake such work of identification.

Cairo.

FRONTAL SINUSITIS: TWO CASES OF DEATH AFTER OPERATION.[1]

BY STCLAIR THOMSON, M.D. LOND., F.R.C.P. LOND., F.R.C S. ENG.,
PHYSICIAN FOR DISEASES OF THE THROAT IN KING'S COLLEGE HOSPITAL
FORMERLY PHYSICIAN TO THE THROAT HOSPITAL; AND
SURGEON TO THE ROYAL EAR HOSPITAL.

WE in England have learned much from the French School of Laryngology in regard to the treatment of frontal sinusitis and one of the most valuable lessons has been the frankness with which unfortunate results have been put on record. In exploring any hitherto neglected corner of the body and in designing suitable operative relief it has unfortunately been impossible always to avoid a rate of mortality which has been greatly diminished after the region has been thoroughly surveyed. In these early investigations one of the principal helps towards progress has been the record of any fatal cases and we all feel indebted to M. Luc for having published his fatal results, as we also do for the help obtained by the record of his successful cases. I am glad to think that the same frankness has also been shown by several of my British *confrères* and deaths following operation on the frontal sinus have been placed on record by Tilley,[2] Burghard,[3] Lack,[4] Milligan,[5] and Logan Turner.[6] I know that many others have occurred and trust that details of them may be published. It is only in this way that we can advance the subject by determining exactly whether the unfortunate results are due to incomplete diagnosis, selection of unsuitable cases, the order of procedure, defects in methods or technique, or the general condition of patients. In neither of the cases which have occurred in my own practice could death be attributed entirely to the operation. The fatal issue was determined by operative interference but in one case it was precipitated by operation on the maxillary sinus before the frontal sinus was interfered with and in the other by an incomplete operation on the fronto-ethmoidal cells, although the frontal sinus itself was quite satisfactorily dealt with.

---

[22] This assortment of species and the relative frequency in which the individual species occur agree fairly well with the results of similar researches recently obtained from natives of Uganda by Castellani and Low (see Parasites and Parasitic Diseases in Uganda, in Archiv fur Schiffs und Tropen-Hygiene, vol. viii., 1904, No. 5).

[1] Translation of a paper read before the Société Française de Laryngologie on May 10th, 1905.

CASE 1.—In August, 1899, a female, aged 27 years, was admitted under my care at the Throat Hospital for bilateral frontal, ethmoidal, and maxillary sinusitis. The Caldwell-Luc operation was first carried out on the left maxillary sinus and the patient left the hospital (Sept. 15th) with the intention of returning later for further treatment. But the day she left she was seized with acute pain round the left eye and on the left side of the head; there were epiphora and swelling of the eyelids on that side and on Oct. 6th she saw a medical man who made an incision below the left eye and evacuated pus. When re-admitted to hospital on the 15th she was very weak and worn out with pain and sleeplessness. Both lids of the left eye were swollen and inflamed. There was a small opening below the left eyelid through which a probe passed into the nose. The skin over both frontal sinuses was swollen and tender but not reddened. On the left side of the bridge of the nose there was a raised, reddened, fluctuating area, tender on pressure, and of the size of a sixpence. The temperature varied from normal to 100·8° F. and the pulse was from 70 to 90. The left frontal sinus was opened by an incision which passed through the swelling on the left side of the nose. This was found to be soft inflamed tissue, beneath which the frontal bone was bare. This was chiseled through and the frontal sinus was found to contain polypoid material. The naso-frontal canal was considerably enlarged and the cavity packed with gauze. The wound was not closed and the packing was changed daily. The operation was followed by what proved to be a deceptive calm. For nearly three weeks the notes report that she was "doing well." The temperature, pulse, and respiration were normal and the wound "looked healthy." Then neuralgia on the opposite—right—side of the face was complained of, the forehead became puffy and œdematous, the right frontal sinus tender, and the right eyelids swollen. The left eyelids were also slightly œdematous. It was evident that extension of mischief was taking place around the already opened frontal sinus and that a subacute infection was spreading from the unoperated one (the right).

On Nov. 16th a second operation was performed. A median vertical incision nearly four inches in length was made in the forehead. This was connected with the wound over the left frontal sinus and with a similar incision made over the right sinus. On reflecting the two triangular flaps the frontal bones were found carious over a semicircular area extending to a radius of one and a half inches from the fronto-nasal suture. In removing all this necrotic bone the rim and part of the roof of each orbit were removed and as part of the posterior wall of the frontal sinus was bare the dura mater over the left orbit was exposed. Polypoid hypertrophies were removed from the right frontal sinus and the recent granulations were scraped from the left. The fronto-nasal ducts were enlarged by freely curetting the ethmoid cells. The frontal septum was not interfered with, although part of it was seen to be carious. The vertical incision only was closed with sutures and each horizontal wound was lightly packed with cyanide gauze. Again there came a period of deceptive comfort. For a week the patient was easy and all went well. Then came pain in the right temporal region and a fluctuating swelling in the right infra-orbital region. On incision pus was evacuated and bare bone detected. Evidently in the right ethmoidal labyrinth there was retention and infection. The ethmoidal cells on the right side were therefore again freely curetted from the frontal wound, part of the os planum being removed. After another week of apparent well-being the temperature rose to 103·4° on Dec. 4th, the patient complained of occipital headache, and became delirious at night and heavy and irritable by day. Still the wounds looked perfectly healthy, there was free drainage into the nose, and no puffiness or tenderness was detected anywhere. It was apparent that the septic process had not only passed through the bones of the skull but was threatening, if it had not already attacked, the meninges. Yet one more attempt was made to limit the septic invasion. On Dec. 5th the median vertical wound was reopened and the skin flaps were reflected. The frontal bones were found carious and were removed in the space included in a semicircular area with a radius of from one and a half to two inches from the root of the nose. This not only cleared away the posterior (cerebral) wall of each sinus but exposed the dura mater containing the superior longitudinal sinus. The septum between the two sinuses was removed as well as the orbital plates of the frontal, so that the contents of the orbit were in contact with the dura mater. No improvement followed this last effort to check infection. Although the large area of the wound looked well and the exposed dura mater began to be covered with small granulations, the symptoms of lepto-meningitis increased and after nine days of irritability, delirium, epileptiform seizures, drowsiness, and coma the patient died on the 13th, three months from the onset of symptoms and two months from the first opening of the left frontal sinus.

There was no post-mortem examination, but it was evident that meningitis was the cause of death following on osteomyelitis, due to septic absorption from chronic suppuration in the frontal and ethmoidal sinuses.

The following points appear noteworthy in the above case: (1) the traumatism caused by the Caldwell-Luc operation performed on the left maxillary sinus stimulated the latent suppuration in the ethmoid and frontal cavities of the same side; and (2) surgical treatment of the left frontal sinus led to septic absorption from the chronic suppuration going on in the frontal and ethmoidal sinuses on the opposite side.

CASE 2.—A girl, aged 17 years, came under my care in King's College Hospital in June, 1902, for chronic suppuration in all the accessory sinuses of the nose. She had previously attended the ophthalmic department, complaining of swelling above and below the right eye, with some pain. She first noticed pain 18 months previously and the swelling commenced nine months later. The pain was sharp and neuralgic but not constant, being sometimes absent for a week at a time. She had neither cacosmia nor anosmia and had paid little attention to the fact that she had a chronic discharge of "matter" from the nose. There was no diplopia. The examination of the eyes was negative but, as is shown in the illustration (Fig. 1), they appeared to be pushed apart by the broadening below the root of the nose. The maxillary sinuses were first drained through the tooth sockets. On June 13th, 1902, the right frontal sinus was opened by an Ogston-Luc operation; numerous polypoid hypertrophies were cleared away (Fig. 2) and the fronto-nasal duct was enlarged. Towards the end of the operation a sudden eruption of pus was noticed near the infundibulum. Its source could not be detected; there was no recurrence of it, and as the frontal sinus had been freely exposed it was concluded that it was simply some pus which had welled up from the nose. The wound was flushed out, only partially closed by stitches, and lightly packed with iodoform gauze, which was left projecting from the inner corner of the wound. As in the previous case, there followed a period of deceptive calm. For ten days the patient continued to eat and to sleep well. The gauze packing was changed daily; the discharge on it rapidly diminished and became mucoid; the drainage into the nose was so free that lotion easily passed down the fronto-nasal canal, and the patient could readily blow air up through it. The sinus was filling with some healthy-looking granulations, the pulse and temperature were normal, the patient got out of bed for a few hours, and nothing could promise better. Then some headache was complained of and tenderness and a puffy swelling were detected over the forehead.

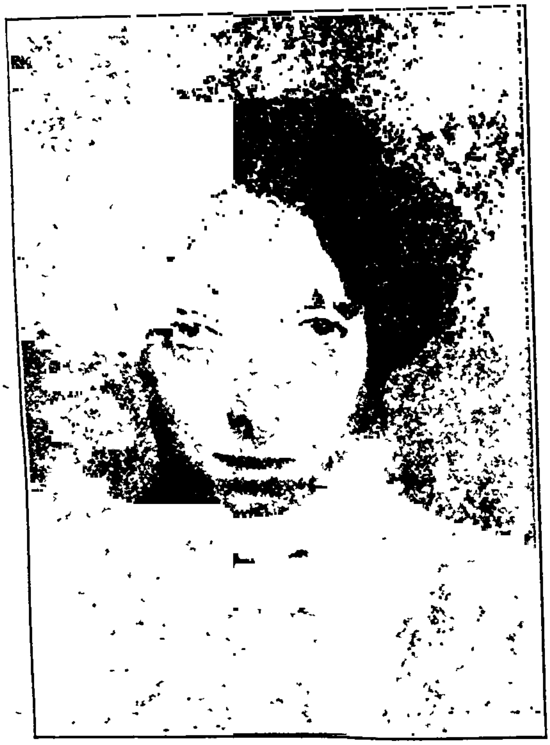
FIG. 1.

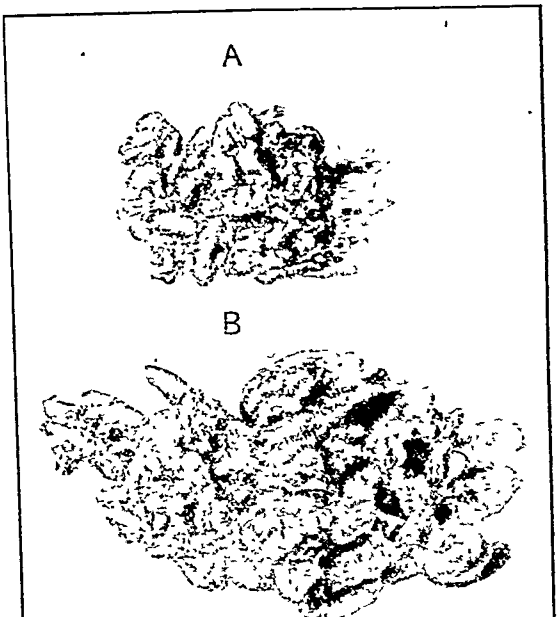


Showing broadening at the root of the nose in Case 2.

On June 26th—i.e., 13 days after the first operation—the patient was anæsthetised and a vertical median incision was made (as in the first case) so as to reflect up a triangular flap of skin from the right side of the forehead. The puffy swelling was found to be simply œdema; there was no collection of pus. The fronto-ethmoidal region was therefore more carefully explored and two long tunnels were discovered, one running backwards below the floor of the frontal sinus as far as the sphenoid and the other running outwards below the floor as far as the external angular process. They were lined with polypoid hypertrophies and it was evident that it was from one of these digitations that the sudden eruption of pus took place at the end of the first operation. They were well curetted. While the septal wall of the sinus was being cleared a portion of bone broke down and so made an opening into the left frontal sinus. As a large quantity of pus escaped the left sinus was freely opened and treated as the right had been and particular care was taken not to overlook the long fronto-ethmoidal cells. On this side also they were found running outwards and also as far back as the sphenoid, forming a double roof to the orbit, a sort of honeycomb partition between the frontal sinus and the orbit. The fronto-nasal canal on the left side, which was blocked with polypoid growths (Fig. 2), was well cleared and the wound lightly packed but only partially stitched up. Again, there was a period of apparent progress but at the end of another 13 days there was puffiness of the right upper eyelid and on passing a probe along the wound in the direction of the external angular process a pocket of pus was discovered and a piece of bare bone was felt. On July 11th this collection was exposed and the underlying bone was found necrosed and removed. The whole of the orbital plate was loose and was taken away and another ethmoidal digitation was exposed running backwards and outwards behind the one already cleared. The patient again appeared to be doing well but owing to my enforced absence from London I had to transfer her to the care of my colleague Mr. F. F. Burghard. Fortunately she could not have been in better hands, for he is a skilled laryngologist as well as general surgeon. On August 8th he had to perform an operation on the left side similar to the last one I had carried out on the right. The patient remained under Mr. Burghard's care for more than a year, during which time alarming symptoms recurred several times, to be relieved by evacuation of pus in the fronto-ethmoidal regions or even in subdural abscesses.

When I saw her again in the autumn of 1903 the frontal sinuses appeared obliterated, but there was a suppurating sinus at the inner corner of each frontal incision and at the outer corner of the left. I could not think they originated from any ethmoidal cells, so freely had they been dealt with, and my surprise therefore was great when the fronto-ethmoidal area was again laid open to discover more suppurating sinuses far back in the remains of a partition between orbit and frontal sinus, and one large tract low down in the remains of the division between the right and left side—a kind of supernumerary central frontal sinus but really a large fronto-ethmoidal cell. Again I had, for personal reasons, to hand over the case to my obliging colleague. He also was astonished that any ethmoidal recess could have escaped attention. In spite of his care further purulent collections took place, subdural abscesses and meningitis developed, and the patient died about one and a half years after the first operation.

FIG. 2.



Polypoid hypertrophies of the mucous membrane from the right (A) and the left (B) frontal sinuses in Case 2. Life-size drawing.

In this case the maxillary sinuses were drained for some time before the frontal cavities were opened; when the latter were operated on they were opened completely; free drainage was established into the nose; the cavities were lightly packed; and the skin incisions were only partially closed. The complications which occurred therefore could not be attributed to incomplete operation on the frontal sinuses, premature closure of the wound, insufficient nasal drainage, too light packing, nor yet to reaction due to operation on the maxillary sinus. I think it is clear the troubles were all due to the fact that at the time of this operation—it is now three years ago—I had not realised the importance of thoroughly treating the fronto-ethmoidal cells nor was I prepared to meet with such a large, tortuous, and irregular labyrinth. Even had I been prepared for this, I would not have known how to deal with it satisfactorily, for Killian's method of operation was then unknown to me. In both these cases it is clear that the key of the whole matter lies in successfully dealing with the ethmoid. A simple suppuration in the accessible frontal sinus, with its dependent ostium, is much more easily dealt with than suppuration in the deep, irregular, and thin-walled fronto-ethmoidal galleries, and I think our most brilliant cases have been those in which there has been little or no accompanying suppuration in the ethmoid.

The following conclusions may be drawn from these two cases:—1. In cases of multisinusitis it is well to drain the maxillary cavity some time before the frontal is operated upon. Both cavities may be operated on at the same time; but if only one sinus is operated on at a time it should be the frontal sinus, the lower cavity being drained until it can be opened. 2. In spite of free opening of the frontal sinus, the establishment of a large communication with the nose, and the avoidance of closure of the external wound a slow infection of the bone may take place leading ultimately to infection of the meninges. This may even be started in suppurating cavities on the *opposite* side to the one operated on. 3. The local condition of the wound, as well as the pulse, temperature, and feelings of the patient may fail to indicate the onset of mischief. After one to three weeks this is revealed by headache, pain, tenderness, and puffy swelling on the forehead or around the eyes. 4. When septic osteo-myelitis has started the most vigorous measures may fail to arrest it. It may last one and a half years before terminating fatally. 5. The chief danger appears to lie in the ethmoidal labyrinth, owing to its anatomical irregularities and to the difficulty of treating them satisfactorily. 6. Up to the present the operation which best meets these difficulties is that of Killian. In many cases a preliminary endo-nasal operation on the ethmoid is advantageous.

In conclusion I would point out that these two cases occurred six and three years ago and that in the meantime the study of fronto-ethmoidal suppuration has been greatly advanced. At the present time the subject is very much to the fore and I feel we are approaching a time when the condition can be treated with more certainty and safety. Meanwhile it is not free from anxiety and danger. These two cases may serve as a warning and as a guide to those who have not met with such complicated conditions and they go far to confirm the action of Dr. Luc in adopting Killian's modification of his own operation.[7]

Queen Anne-street, W.

A CASE OF PAROTITIS DUE TO THE PNEUMOCOCCUS.

BY S. HASTINGS, M.B. LOND., F.R.C.S. ENG.,
CASUALTY SURGICAL OFFICER, THE MIDDLESEX HOSPITAL;
AND
W. T. HILLIER, M.R.C.S. ENG.,
ASSISTANT IN CLINICAL LABORATORY, THE MIDDLESEX HOSPITAL.

ON May 13th, 1905, a man, aged 55 years, attended the out-patient department of the Middlesex Hospital complaining of swelling of the right side of his face. He stated that the swelling commenced with slight pain during the night of May 11–12th and that since that time he had been troubled with a continuous but not severe aching pain in the region of the swelling and, further, that it hurt him to open his mouth. On looking at the patient's face it became clear that the swelling was due to a general enlargement of the right parotid gland and firm pressure on the gland elicited slight tenderness. When the patient opened his mouth the septic condition of that cavity became evident. The teeth, especially the molars, were much decayed and there was a large amount of tartar, notably on both aspects of the lower incisors. In addition there was a certain amount of pyorrhœa with retraction of the gums, more marked in the case of the lower jaw. The left salivary papilla presented a normal appearance, but the right papilla was reddened, bled readily when touched, and was slightly more prominent than that of the opposite side. The patency of Stenson's duct was assured by noticing several drops of saliva exude from the papilla while the mouth was being examined.

On May 15th the patient returned to the hospital; the swelling on the right side of the face was much less but the left parotid was now for the first time noticed to be slightly enlarged. All pain had ceased. The right salivary papilla was only slightly inflamed and the left one seemed quite normal. On the following day all swelling on the right side had disappeared and the enlargement of the left parotid was only just perceptible. The patient's temperature was taken on this occasion and was found to be 98·6° F. and his urine tested for albumin gave a negative result. Five days after his first coming to the hospital all swelling and pain had disappeared from both sides and he seemed to have regained his usual health.

The treatment had been very simple and consisted of a purge, a mouth wash of mercury perchloride solution (1 in 2000), and a fomentation over the swollen parotid gland. Bacteriological examination was made of the saliva from the right gland on May 13th, when the patient first came to the hospital. The saliva was obtained by rubbing an ordinary "throat swab" over the salivary papilla after the inside of the cheek had been carefully swabbed. A nearly pure culture of a diplococcus was obtained from this in 48 hours' incubation at 37° C. It retained the stain when treated by Gram's method and it possessed a capsule. On May 15th, when the patient next attended, the mouth was swabbed out and then some saliva was collected from the right duct directly by passing a sterilised capillary tube into it and expressing the secretion from the gland. A "swab" was also taken from the left cheek over the duct on that side. The fluid from the right side furnished a pure culture of a diplococcus precisely similar to the organism obtained at first. Tubes inoculated from the left cheek remained sterile. Subcultures made from the second set of tubes showed that the organism would not grow upon or in gelatin at 20° C., or on potato or on inspissated horse serum at 37° C. On agar it appeared in the form of numerous discrete, minute, round, transparent colonies; but it would not grow under anaerobic conditions. It failed to ferment glucose but milk was curdled by it. Hanging drop preparations of broth culture after 24 hours showed numerous diplococci and short chains of 4–12 elements. Two experiments of intraperitoneal injection of mice with broth cultures failed to show pathogenic action. A third bacteriological examination of the patient's saliva a few days later showed the presence of the same organism but the colonies obtained were very much fewer in number.

There appeared to be no reason to doubt that the parotid swelling was inflammatory in nature and we would attribute it to the diplococcus which we obtained in pure culture in the secretion of the gland. This organism we recognised as pneumococcus but of a strain possessing little virulence.

ASPIRATION IN DISEASES OF THE EAR AND THE NOSE.[1]

BY DR. MED. R. SONDERMANN.

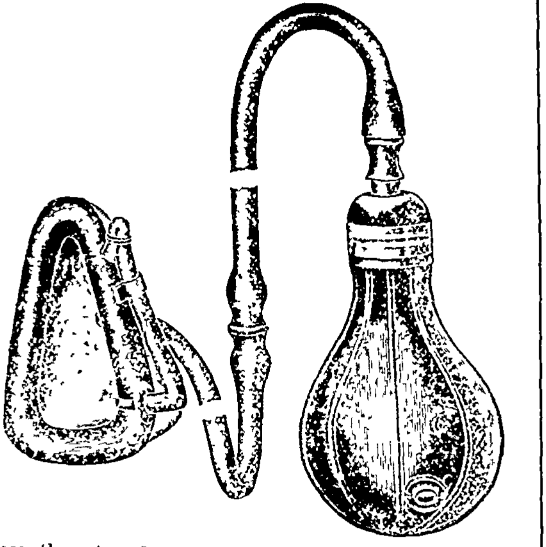
WHENEVER hollow organs of the human body are attacked by diseases accompanied by suppuration the evacuation of the pus is, beyond any doubt, the most important task of the medical art. If such an evacuation can be fully effected we not only notice an improvement but very frequently recovery ensues without the help of any other measures. The more deeply the pus is situated the more difficult it is, of course, to evacuate it, and especially is this the case in suppurative inflammations of the nose and the ear and their accessory cavities where there has until now scarcely been known a method by which thorough fulfilment of this requirement could be effected. Irrigation, which is employed for this purpose after more or less important surgical interference in cases of empyema in the antrum of Highmore and less frequently in other accessory cavities, is impossible in cases of acute suppurative inflammation of the middle ear and of the mastoid process as long as there only exists a small opening in the membrana tympani. In the same way blowing through the Eustachian tube and through the external meatus to evacuate the pus has proved to be of doubtful success only. Greater advantages may be derived from the aspiration method, although until now it has but rarely been applied in the therapeutics of diseases of the ear. In Politzer's handbook[2] this method has been cited among those of medical investigation and treatment, but according to the passages referred to its employment is rather rare and as regards the treatment of acute suppurative otitis media its use has not been mentioned at all.

---

[7] At the meeting at which the above paper was read three other cases of death were reported after operation on the frontal sinus. In one (Dr. Mermod of Lausanne) the patient succumbed to acute lepto-meningitis four days after operation by Killian's method. In the two others (Dr. Castex of Paris) death from meningitis occurred several weeks after operation.

[1] Sondermann: Suction applied to Diseases of Cavities and to Lupus, a paper read [illegible] hysicians and naturalists, Breslau, 1904; Eine [illegible] e der Nasenerkrankungen, [illegible] 1905, i.; Saugtherapie bei [illegible] unde, 64, i.

Hartmann[3] only refers to the rarefaction of air in the external meatus in connexion with the treatment of noises in the ear in cases of chronic otitis media without secretion. Nor do we find it mentioned in the article by Blau[4] in the Encyclopædia of Diseases of the Ear. Ostmann[5] in the same work only states that rarefied air is but little applied in these cases because it has hitherto been used only in an inefficient way and without satisfactory results. In cases of disease of the nose and its accessory cavities the suction method, as far as I know, has not yet been therapeutically applied at all.[6] All suction methods applied to the ear agree in requiring a complete closure of the external meatus. This is attended with many difficulties. The external meatus is very sensitive in suppurative diseases and the introduction of the tube is therefore, especially if repeatedly applied, rather painful, which renders it difficult to make it fit tightly. The space over which the rarefaction of air is extended is very small, so that too strong an effect may easily be produced. All these difficulties are met by my apparatus (*vide* illustration[7]) which not only hermetically closes the external meatus but also covers in the whole ear, including the auricle. It consists of a hollow mask open at one side and surrounded by a hollow ring of hardened rubber, and by means of an elastic tube it is connected with the suction ball. The latter, as well as the elastic tube, possesses a valve by which the air can only pass outwards after the suction ball has been compressed. As the mask is of triangular shape it can also be applied to the nose if required. By a slight pressure it fits almost hermetically on the skin and can therefore be applied easily at any time by the patient himself without the help of another person. There is no contact whatever with the external meatus and its contents and there is scarcely any danger to be feared from too strong a suction, as the rarefaction of air is spread over a relatively large space and cannot exceed the amount corresponding to the elasticity of the suction ball. In cases of acute suppuration a slight aspiration will be found sufficient in order to evacuate the pus from the middle ear and even from the cells of the mastoid process into the external meatus. On the other hand, in cases of chronic empyema a stronger suction ball can be used, and especially when the membrana tympani or the ossicles are partly or entirely missing. Then it will be possible to exert a more intense suction, by which less fluid secretions are discharged if the nidus is connected with the middle ear. To this must be added that the walls of the cavity are artificially rendered hyperæmic. The importance of this process has only been recognised within the last ten years and its recognition is especially owing to the articles of Professor Bier of Bonn. This is not the place to dwell upon his statements in detail but I should like to point to his comprehensive monograph of Bier, Hyperamia als Heilmittel,[8] in which he enters fully into the actual state of our knowledge of this process. The assertion that hyperæmia possesses a great remedial effect in a great many cases can scarcely be disputed any longer, although it cannot yet be definitely stated which kind of hyperæmia—whether active, passive, or mixed—will be applied with the best effect in every individual case. We must suppose that in the forms of disease under discussion both veins and arteries take part in the augmented blood-supply produced in the walls of the middle ear by the negative pressure caused by aspiration. If this be a fact a mixed hyperæmia is doubtlessly effected. Moreover, it must be added that by the suction method very often secretions are loosened and even discharged which, being of a more adhesive nature, are not affected by irrigation at all or only with great difficulty. After suction, however, the irrigation of the ear may be much more effective. These different therapeutical effects, however, are the more valuable as the patient himself is able to manage the application quite comfortably; this fact facilitates in a high degree the use of this method, for in order to be successful the applications must be often repeated. In two cases of acute suppuration of the middle ear in which the mastoid process was also affected by the disease, as was shown by the swelling and the tenderness, and in which the intense pain continued in spite of the free and copious discharge of pus, the aspect of both the cases changed at once after the pus had been evacuated several times a day by aspiration. The pain and tenderness ceased almost directly as well as the discharge and the patients rather liked the aspiration because they felt an immediate relief in both head and ear. Such an instantaneous effect is comprehensible because pus was also evacuated by suction from the mastoid process, for the discharge of pus in one sitting was far too abundant to have been extracted from the tympanic cavity only. This seems also to be proved by the instantaneous decrease of tenderness which can scarcely be attributed only to the "dry-cup" effect of the apparatus. The result of the treatment has also been satisfactory for the condition of the ears after the application was by no means worse than it had been before. It appears from this that the ears had not in any way been injured by the suction method although it had been frequently applied. On the other hand, it is scarcely to be feared that any harm should result as the suction force required for evacuating pus is but slight. There is no doubt but that the patients are treated in this way far more pleasantly than by attempts at removing pus by compressing the air in the Eustachian tube or in the external meatus.



Chronic suppuration of the ear has been treated by me with methodical aspiration in a great number of cases and the advantages mentioned above could always be recognised and the pain was relieved at once and very often disappeared altogether. In several cases where there was no membrana tympani left but the mucous membrane was much thickened and discharged pus a change for the better was noticeable after applying the suction method for three minutes five times a day. All other therapeutic measures, with the exception of syringing with lukewarm water, were intentionally excluded. The condition of the mucous membrane daily improved until after some weeks the discharge entirely disappeared. It is obvious that in cases complicated by a polypus the latter had to be removed by surgical interference. My statements prove that the methodical application of suction can be considered as an effective therapeutic measure in suppurative diseases of the nose and that, moreover, it will henceforth be more frequently possible to effect a satisfactory cure without operation than has hitherto been the case. There is little risk that in this way a necessary operation should be deferred too long because it will soon be easy for the physician to recognise whether by the application of the suction method an essential change for the better can be effected or not. In a similar way an effect may be produced on the middle ear by aspiration from the Eustachian tube. In this case the same apparatus can be used as for application in cases of nose diseases. The rarefaction of air will by no means become so strong as to cause a hyperæmia which might be injurious. But, on the other hand, it is to be supposed that the mucous membrane of the tube, and especially of the entrance of the tube, will be favourably influenced by the suction. How far this method is able to supplement Politzer's method, or even to replace it in some cases, must depend on experience. But it must be considered as an advantage of the former that the patient easily learns how to apply it and that the aspirating power can only be raised to a certain degree which is precisely regulated by the elasticity of the suction ball.

[4] Berlin, 1900.

[5] S. 215.

[6] Having finished my essay, I find in the Medicin Klinik a report on my work concerning this method in which it is stated that Professor Seifert, of Wurzburg, has already mentioned a method for sucking accessory cavities. For this purpose he introduces the olive of a previously compressed balloon of caoutchouc hermetically into one nostril, while at the same time the other must be closed by a finger, and then he uses the act of swallowing for producing a closure from behind. But it seems that this method has not frequently been applied and this has doubtlessly only been the case because, used in this way, it could by no means prove successful.

[7] The apparatus is manufactured by Messrs. Kuhne, Sievers, and Neumann and it is to be obtained from Messrs. Mayer and Meltzer, 71, Great Portland street, London, W.

[8] Leipsic, 1903.

The apparatus used for the suction method when applied to the nose has the same form as the one described above, but, of course, its mask is smaller as the two nostrils and their immediate neighbourhood only need be hermetically closed.

The suction apparatus applied to the nose.—When the apparatus is applied to the ear the tuba Eustachii may be considered as closed and therefore it is only necessary to close the ear outwardly in order to obtain a space where the air is rarefied; when, however, it is applied to the nose it is necessary to effect a thorough closure of the throat as well. Although in this case the application of suction is consequently rendered more difficult, and even requires some practice on the part of the physician to cause a suction effect with every patient, yet even here it will be an exception for the patient not to be able to learn to apply the suction apparatus to his nose himself. This is no less important here than when applied to the ear, for this method can only be crowned by success when sufficiently frequently repeated.

There are two possible ways of closing the nose towards the throat: (1) by making the patient pronounce the vowels, and especially *i* (long German *i* = English ee), and (2) by swallowing, as has been used for the same purpose by Politzer. It is always advisable to try first the former method. The vowel *i* (ee) must be pronounced in a strong manner and as clearly as possible. This latter point is of great consequence as a great many patients are inclined to produce a sound more like *e* (a) than *i* (ee), which very often spoils the effect. Should this method be of no avail, which will more frequently be the case with the old than with the young, it will be advisable to make the patient perform a forcible act of swallowing which is sure to prove successful. Very often it will be noticed that patients claim to perceive at the same time a deaf feeling in the ear. This is caused by the fact that the tube which has been opened at the moment of suction has transmitted the rarefaction to the middle ear. By swallowing without any simultaneous suction this deaf feeling will be removed at once. I can only state that though I have very frequently applied the suction method for more than a year, I never perceived the least injurious influence upon the patient. It happens, it is true, that the suction, especially when applied for the first time, makes itself felt in a disagreeable way to the patients and sometimes even they will complain of a headache caused by the aspiration process but the pain will soon be over. If, however, it should continue on the following day, which will be exceptional indeed, a less effective suction ball should be used.[9] If, on the other hand, the mucous membrane (Schneiderian membrane) should show a slightly bleeding spot and if this bleeding should occur at every sitting an interruption of the application will be required but very often this bleeding ceases the following day.

The apparatus is applied to the nose as follows. A small compress of cotton-wool is applied and then the mask is put on the nose and the ball is compressed, and whilst the patient is pronouncing a long *i* or is swallowing the ball is allowed to regain its former size. The aspiration effect is directly noticeable by a strong suction feeling. The mucous membrane, whatever may have been its condition before, markedly swells, becomes red, and is covered with a thin layer of mucous. Both reddening and swelling soon decrease and in cases in which both symptoms existed before they are frequently reduced after the first suction. Besides, it will soon be found that if there are fluid secretions in one or in several of the accessory cavities they have been discharged through their several openings, not always at once, it is true, but very often after the suction has been repeatedly applied and exceptionally not before the following day.[10]

Except in the rare case of occlusion of the excretory duct this effect fails very seldom and therefore we have in suction a method for diagnosing diseases of the accessory cavities scarcely excelled by any other for certainty, simplicity, and ease; however, this is only of value in connexion with the question whether there exists any disease of the accessory cavities at all. On the other hand, it is rather difficult to decide with certainty which of the accessory cavities has been attacked by disease, because it can only exceptionally be known from which side the pus has been discharged. If, even when other symptoms are missing, we must be satisfied with the general diagnosis this disadvantage need not be considered as one of great importance when the suction method is employed. The frequency of its application depends, of course, entirely on the character of the disease; as a rule it has to be applied the more frequently the more copious the discharge of matter or secretions, say, about five times a day. As soon, however, as improvement takes place and continues the daily applications can be reduced until there is no more discharge. In many cases of empyema which did not improve spontaneously I was in this way able to obtain a thorough cure after applying the suction method for about a fortnight. If, however, the improvement is slow the case unquestionably is an old one which has become chronic; such chronic cases always require a longer treatment. Should there be found a polypus or some bony sequestra surgical interference cannot be avoided. As for the other cases, however, the suction method alone ought at least to be tried.

According to my experience this treatment will always be followed by this amount of success, at least, that the pain will be alleviated at once. Therefore the patient will have no objection whatever to undergoing a longer treatment, because after some time he will only need a few minutes for the daily application of the apparatus. The results obtained hitherto justify the hope that in many cases—if not in all—a long, lasting improvement will be sure to be effected. In the same way this method can also be confidently applied in cases of ozæna due to rhinitis atrophicans fœtida. The removal of crusts, which so very often proves rather difficult, is easily managed by aspiration, for after having been loosened by it they can easily be removed by the patient blowing his nose. This has to be done in a correct way—i.e., each nostril must be blown separately and by no means together. In five cases which I treated with the suction apparatus, applying it several times a day, the crusts not only lessened every day but disappeared in two of the above-mentioned cases altogether after one week's treatment; the patients were also fully freed from an empyema of the accessory cavities. Whilst some of these patients were allowed to stop the treatment for a time after the apparatus had been applied for some weeks only, others had to apply it to the nose once or twice a day for months and even for years in order to guarantee the complete cure of their complaint. Strict individualising in these cases as in many others will, of course, be required according to the character of the disease, which may require a more or less frequent application of the suction apparatus.

It must be mentioned that the hyperæmia caused by the suction treatment of the nose as well as of the ear has a most favourable influence, *especially in cases of rhinitis*; how far, however, the accessory cavities are favourably influenced by it too cannot yet be decided with certainty. Though I am fully aware of the fact that the suction method can scarcely be considered as a never-failing treatment for every disease within so difficult a region as these accessory cavities, I am, however, fully convinced that its advantages are evident enough to range it amongst the medical measures for treating such diseases.

Dieringhausen.

---

[9] A weaker ball should always be used with children.

[10] The position of the antrum of Highmore, which is rather unfavourable for the suction method, can easily be corrected, if necessary, by a lateral position of the head. Also it ought to be noticed that the discharged secretions do not always appear at the anterior nares but frequently in cases of disease of the sphenoid cells, and perhaps even of the hinder ethmoidal cells, they flow into the pharynx and are then only discharged by hawking.

DELAYED CHLOROFORM POISONING.

BY E. W. SCOTT CARMICHAEL, M.B. EDIN.,
F.R.C.S. EDIN.,
ASSISTANT SURGEON TO THE ROYAL HOSPITAL FOR SICK CHILDREN, EDINBURGH;

AND

JAMES M. BEATTIE, M.A. NEW ZEALAND,
M.D. EDIN.,
LECTURER ON PATHOLOGICAL BACTERIOLOGY AND SENIOR ASSISTANT TO THE PROFESSOR OF PATHOLOGY, UNIVERSITY OF EDINBURGH.

THE condition of delayed chloroform poisoning has not yet received general recognition by surgeons, though its importance can hardly be over-estimated. Stiles and McDonald[1] in a recent paper have drawn special attention to the subject and have presented a typical clinical and pathological picture of the condition. A case has recently come under our attention which corroborates very largely their observations but which presents also some additional points of interest. The literature on the subject has been so fully gone into in the above-mentioned paper that we deem it unnecessary again to deal with it.

The patient, a girl, aged three and three-quarter years, on the recommendation of Dr. R. Cross of Linlithgow was admitted to McKay Smith ward on April 8th, 1905. Nine months previously there was a history of an injury resulting in stiffness of the right elbow-joint which had become more swollen and painful after treatment by a bonesetter. On admission there were general synovial thickening of the joint and marked enlargement of the olecranon process of the ulna. There was no local abscess or sinus. The joint was excised by a posterior incision on April 11th. the upper end of the ulna and the head of the radius being removed. The total duration of chloroform anæsthesia was 30 minutes, five drachms of pure chloroform being used. No carbolic acid or strong antiseptic was used during the operation. Nothing exceptional was noted in the child's condition after operation, the pulse being, however, somewhat small, 132 per minute. During the afternoon she was sick and vomited once some bilious fluid and remained somewhat restless for the rest of the day. On the 12th the house surgeon (Dr. H. N. Fletcher) noted that she had had a restless night and vomited twice some greenish bilious material. She was very pale and complained greatly of thirst, the pulse being small and weak. The temperature remained slightly subnormal. The wound was examined and appeared to be healthy, there being no sign of hæmorrhage. A saline infusion given per rectum was not retained. A repetition of saline injection on three further occasions was retained. The child continued to be very restless all day and complained greatly of thirst. About 6 P.M. she became comatose, vomiting a considerable quantity of coffee-ground material two hours later. She never regained consciousness up to the time of her death at 5.30 A.M. on April 13th, 42 hours after operation. The temperature remained subnormal from the time of the operation. Although very restless the child did not cry out or shout. Her pupils remained markedly dilated throughout.

Necropsy.—A post-mortem examination was made on April 14th. The body was that of a fairly well-developed child. Rigor mortis was general. The right elbow-joint had been excised by a posterior incision. The upper end of the ulna and the head of the radius had been removed. The external wound looked perfectly healthy. On opening it up the tissues were blood stained but there was no evidence of pus formation in any part. Portions of tissue were excised from various points and the bone marrow was scraped from the open medullary cavities of the bones for microscopic examination. Both pleural and pericardial sacs were perfectly healthy. There was no glandular enlargement in the mediastinum. The thymus was not enlarged. There was a small amount of post-mortem clot in the right side of the heart. The cavities and orifices were not dilated, nor was there any hypertrophy. The valve segments were competent and quite healthy. The muscle was pale but firm. It showed no naked-eye evidence of fatty degeneration, nor was there any evidence of any interstitial changes. There was a tuberculous gland at the root of the right lung. The whole of the lung tissue was congested. There was no trace of consolidation, nor was there any evidence pointing to a bacterial infection. Apart from the congestion, the lung tissue, the pleura, the bronchi, and the vessels showed no abnormal condition. There was no peritonitis or other abnormality in the peritoneal sac. The stomach contained some altered blood, but no trace of ulceration or erosion of its mucous membrane could be detected. The pancreas showed nothing abnormal. The intestines appeared quite healthy. The mesenteric glands were slightly enlarged, pale in colour, but showed no evidence of tuberculosis. The liver was distinctly and uniformly enlarged. The surface was quite smooth and the colour almost of a canary yellow tint. On section there was seen to be an intense degree of fatty change. Throughout the greater part of the organ this was uniformly distributed, the outlines of the lobules were lost, and no separation could be made out between the central and peripheral zones. There were irregular areas in the right lobe, where the fatty change was not so advanced. Here the lobules could be made out and the fatty change was seen to be most intense at the peripheries of the lobules. No other abnormal change could be made out in the liver. The spleen was not enlarged. It was pale but firm and showed practically no pathological change. Both kidneys were slightly enlarged and were very pale. The capsule stripped readily, leaving a smooth surface. The stellate veins were not specially prominent. On section there was slight swelling of the cortex both superficial and deep. It showed an intense pallor, but the yellow tint so marked in the liver was not present. The Malpighian bodies were not prominent. The pyramids showed no abnormal condition. The vessels were quite healthy. There was no evidence of any septic foci or any evidence of tuberculosis. The suprarenal capsules were both enlarged, firm, and of a bright canary yellow tint. On section the yellowish colour extended throughout the cortex and the medulla. The bone marrow was pale but showed no naked-eye change. The brain was not examined.

Histology of the lesions—Portions of all the organs were fixed in a saturated solution of perchloride of mercury or in a 10 per cent. solution of formalin. Sections were stained with hæmatein and eosin, methylene blue and eosin, and specially for fat with sudan iii., scharlach R., and osmic acid. Others were prepared by Marchi's method and counterstained with licht grün or with rubin and orange.

The striation of the fibres of the heart was distinct and there was no segmentation of any of them. At places there was a slight amount of granularity in the body of the fibre but no fat could be demonstrated. There were no excess of pigment and no evidence of any increase in the interstitial tissue. The nuclei of the muscle fibres stained perfectly with hæmatein. The blood-vessels were not congested nor did their walls show any thickening. No fat could be demonstrated in the endothelial lining of the vessels

The capillaries in the alveolar walls of the lungs were dilated to a moderate degree but there was no marked evidence of acute congestion. The alveoli contained a few catarrhal cells but no inflammatory exudation was found in any part of the lung. The bronchi were quite healthy, the ciliated epithelium was intact, there was no desquamation of the epithelium, nor was there any congestion of the vessels in the bronchial walls. Fat was present in the form of minute droplets in many of the cells in the alveolar septa (Fig. 1). It was not easy to determine the exact nature of these cells because many of them were much swollen and obscured by the fat granules. Some of them appeared to be connective tissue cells, but undoubtedly a great number were the endothelial cells lining the alveolar capillaries. In some of the vessels a few free cells containing fat granules were seen but in none of the vessels was there any large accumulation of fat such as one finds in cases of fat embolism. Fat globules were also seen in some of the cells lining the alveolar spaces. Some of the cells containing fat which were found in the alveolar walls were probably cells which had migrated from other parts or which had passed by the lymphatic channels to the lung. That this passage was taking place is seen by a study of the spleen and the lymphatic glands. Still we are forced to the conclusion that a great deal of the fat was a local production formed in the cells by the direct action of the poison.

In regard to the liver, in sections in which the fat had been dissolved out by chloroform there was an irregular swelling of the liver cells, leading to in many places an almost complete closure of the capillaries between the rows of liver cells. The liver cells were markedly vacuolated, and in those in which the cytoplasm was not wholly destroyed it was very granular and formed bridges separating the vacuoles from one another. The nucleus in all of the cells stained perfectly with hæmatein. In freshly prepared sections stained for fat it was seen that all the cells from the centre to the periphery of the lobules were crowded with fat globules. The globules were mostly small but at places large globules almost completely filling the cells were seen. In certain areas where to the naked eye the fatty change appeared less marked it was seen on microscopic examination that all of the cells contained fat but that it was specially abundant in the peripheral zone of cells and that there the globules were larger than at the centre. Fat was also seen in the cells lining the bile capillaries and in the endothelial cells of the blood capillaries. In a few of the hepatic veins there were cells containing a good deal of fat and these cells were undoubtedly secreting cells of the liver. We were not able to detect free fat in any of the vessels. Apart from the fatty change in the liver cells there appeared to be no other abnormal condition of the liver. There was certainly no increase of fibrous tissue nor any cellular increase in the portal spaces—in fact, nothing lending any support to the view that some other pathological change preceded the acute fatty degeneration.

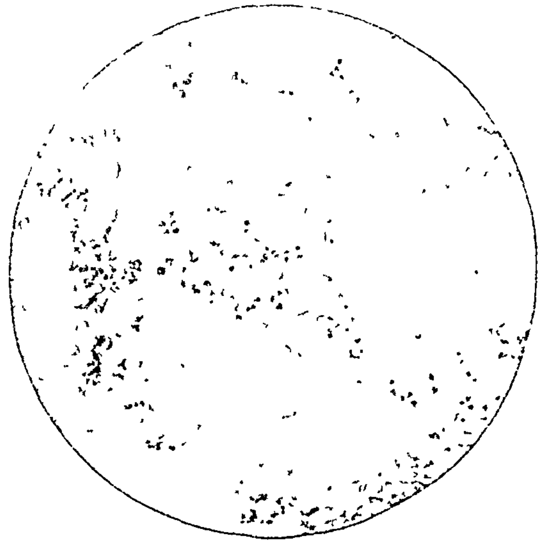
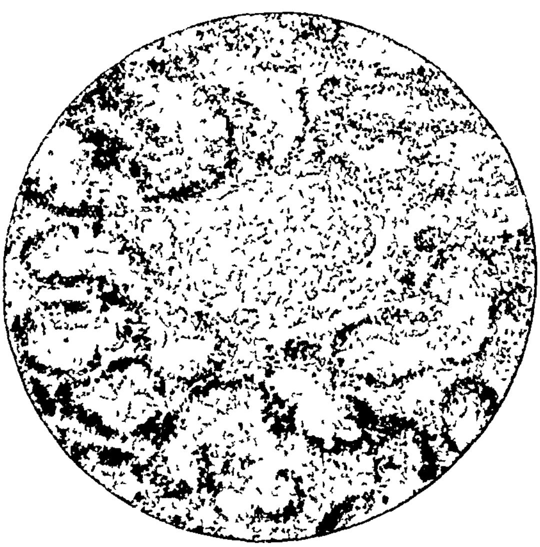
FIG. 1.



Lung of child. × 200 diameters.

FIG. 2.



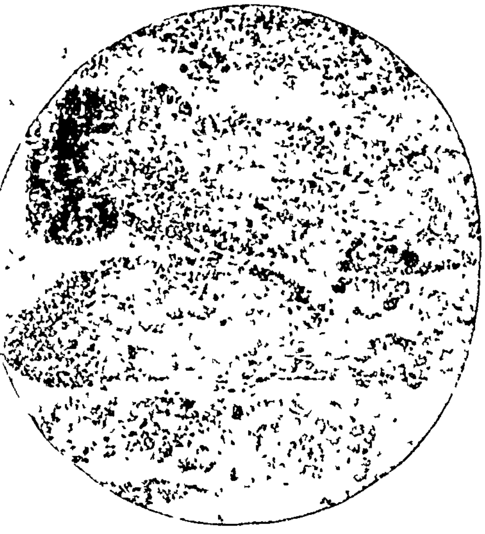
Kidney of child. × 200 diameters.

As to the kidney, the cells in all of the tubules, collecting as well as secreting, were swollen and granular and in paraffin sections there was very distinct vacuolation. The nucleus in most of the cells stained perfectly, though in some of the cells of the convoluted tubules there was karyorrhexis. There was no evidence of chromatolysis. In very few of the tubules were there any desquamated epithelial cells. There was very extensive fatty degeneration in almost every cell of every tubule. Only here and there a few of the collecting tubules showed no fat. The fat globules varied much in size but were mostly small and were situated in the deeper part of the cells (Fig. 2). The glomerular capillaries were congested but there was no evidence of any cellular increase in the tufts. The epithelium of Bowman's capsule showed no proliferation In a few of the Malpighian bodies between the tuft and Bowman's capsule there was a granular exudation. Fat in the form of very fine globules could be demonstrated both in the endothelium of the capillaries and in the epithelium lining Bowman's capsule.

The larger vessels of the interstitial tissue and the straight vessels in the medulla were dilated and filled with blood The larger veins and arteries showed no special changes. No fat either in the form of free globules or as globules in the cells could be demonstrated in them.

In the case described by Stiles and McDonald no change was discovered in the suprarenal capsules. In our case there was very extensive fatty degeneration of the whole of the glandular cells. This degeneration was most marked in the cells of the cortex and especially of those near the surface (Fig. 3). There was also quite definite fatty degeneration in the endothelial cells lining the capillaries.

FIG. 3.



Suprarenal body of child. × 200 diameters.

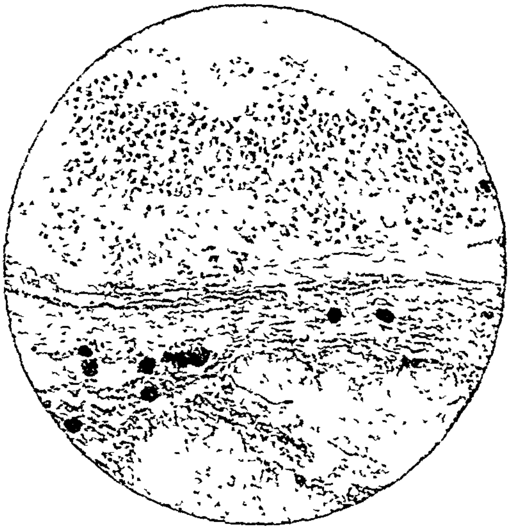
With regard to the mesenteric glands, unfortunately these were the only glands examined. In the lymph spaces at the periphery of the lobules there were numerous cells containing fat. So abundant were these that they mapped out very distinctly the lobules of the gland. The gland cells proper showed no change, nor could any change be made out in the vessels. It seems, therefore, most likely that the cells containing fat were migratory and had passed by lymphatic channels to the glands.

Some of the smaller arteries of the spleen showed marked swelling and hyaline degeneration in their middle coats. There were a few large mononucleated cells in the lymphatic spaces containing fat globules. No other abnormal change was made out.

In the pancreas there were scattered irregular areas of necrosis in which the nuclei did not stain with hæmatein, but as the post-mortem examination was not made till several hours after death no importance can be attached to these. The rest of the cells, both of the gland itself and of Langerhans' islets, showed no abnormal condition. No at could be demonstrated.

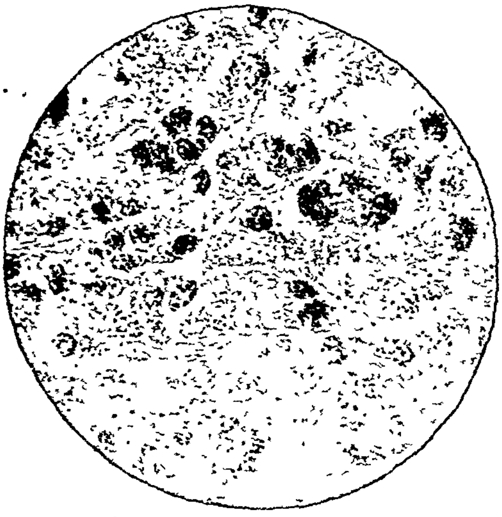
There was no abnormal condition in either the muscular or submucous coats of the stomach. The secreting cells showed marked changes. In sections prepared by the ordinary paraffin process the cells, both central and peripheral, were swollen, granular, and vacuolated, but the nucleus *stained perfectly* throughout. In sections specially stained for fat the peripheral cells were filled with globules which reacted to all the "fat" stains, while the central cells also showed a *moderate* degree of fatty degeneration (*Figs.* 4 and 5). The endothelial cells of the capillaries between the glands were swollen and contained numerous fat globules in a state of fine division.

FIG. 4.



Stomach of child. × 45 diameters.

FIG. 5.

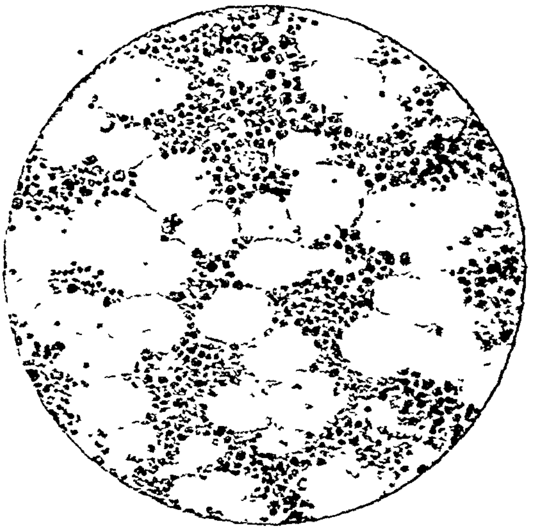


Stomach of child. × 200 diameters.

The bone marrow (*Fig.* 6) was taken from the femur. There was very little, if any, proliferation of the blood-forming elements of the tissue. The *fat cells* were present in a greater amount than is usually found at this early age. The ratio of nucleated red *cells, both* normoblasts and megaloblasts, to the formative cells of the white series was rather larger than normal. There was certainly no increase, but if anything a diminution of the leucoblastic elements. Comparing the specimens from this case with those of a child of the same age also with tuberculous disease but who died from diphtheria the contrast was very striking. In the latter case there were an almost entire disappearance of the fat cells and a very complete leucoblastic transformation of the tissue. The changes then in the *bone marrow were similar to* those observed by Dr. W. E. Carnegie Dickson, to whom we are indebted for examining and reporting on the specimen, in other cases of tuberculous disease in children. *We need not* specially refer to these, as the work by Dr. Dickson we hope will be published shortly. On the other hand, the changes are entirely unlike those seen in cases where there was a *definitely septic element in the case.*

We very much regret that no examination of the blood was made during life but an *examination of the blood in the* vessels in the bone marrow and in the various organs showed very few *leucocytes* and pointed to a leucopenia rather than a leucocytosis accompanying any septic condition. Pieces of tissue were cut out from various places in the neighbourhood of the wound and were examined microscopically. There were various collections of polymorphonuclear leucocytes at places, with areas of hæmorrhage. *No bacteria of any* kind were found though a considerable number of specimens stained in various ways were *examined. The bone marrow* from the opened medullary cavity was also examined. *This shows a hæmorrhagic infiltration and a considerable* invasion by polymorphonuclear leucocytes. No bacteria could be demonstrated.

FIG. 6.



Bone marrow of child. × 200 diameters.

Remarks.—1. *Clinical.*—If we are to accept the view of Nothnagel, Ostertag, and others that chloroform produces the pathological changes indirectly in *the tissues* by destroying the red blood corpuscles increasing anæmia should be a prominent *sign* and one which was markedly noticeable in the present case. Thirst was a marked symptom, the child constantly crying out for drinks. The character of the vomiting differed somewhat from that of most recorded cases. It is interesting *to note that* the child vomited two or three times on the day prior to operation. She vomited on two occasions during the night following the operation some greenish-yellow fluid. There was never at any time any retching. Six hours before her death she vomited some coffee-ground material. We can exclude in this case the mechanical *action* of repeated retching as a cause of the hæmorrhage into the stomach. We are also able to exclude, *as we shall* afterwards show, any septic element in the causation of the hæmorrhage. Delirium, a prominent symptom in most cases, was absent and although marked restlessness was present there was none of *the crying* or *shouting* recorded in other cases. It will be seen that in this case the clinical symptoms *presented* in *many* respects the picture described by Stiles and McDonald, Guthrie, and others. There was no sign of jaundice throughout, although an examination of the urine revealed a slight trace of bile to ordinary reagents. Extreme pallor *was, however*, present to such a degree as to suggest to one of us the possibility of hæmorrhage and the necessity of examining the wound on the day following the operation.

2. *Pathological.*—It will be seen that the pathological appearances were in the main similar to those of the case described by Stiles and McDonald. The main objections to the view that the clinical symptoms and the pathological appearances in these cases are due primarily to chloroform poisoning are founded on the facts that similar symptoms and similar pathological appearances are found in patients who die as a result of fat embolism and in those who are poisoned by chemical agents or by septic products. We must deal with these in turn.

Fat embolism.—It is only necessary to mention this to exclude it. Though the clinical manifestations are very similar in the two classes of classes fat embolism is rarely fatal and one usually has no difficulty in fatal cases in showing large areas of the pulmonary capillaries filled with oil drops. In our case no free oil was found in any of the lung capillaries though careful search was made for it. Unfortunately the brain was not examined.

Chemical agents.—These were absolutely excluded. The preparation of the skin was carried out in the following manner. It was first thoroughly cleansed with lysol (one drachm to 20 ounces of water) and fluid soap, then rubbed over with ether, washed with a solution of carbolic acid (1 in 20), sponged with sterilised water, and a soaking of gauze wrung out of sterilised water was applied for 24 hours. The same cleansing process was repeated before the operation. We cannot imagine that in this method of preparation there could have been sufficient absorption of the chemical agents used to produce any pathological change.

Septic products.—The more serious objection that the death was due to sepsis must be dealt with fully. The clinical symptoms were very similar to those of patients dying from intense septic infection and on clinical grounds alone we admit that the two conditions can hardly be distinguished. The temperature remained slightly subnormal throughout, a point not absolutely against the idea of intense sepsis but certainly pointing the other way. Then again, the pathological changes in the various organs may be exactly simulated in septic cases. Like Stiles and McDonald, we cannot agree with Guthrie that the fatty liver of chloroform poisoning can be distinguished from the fatty liver of sepsis. One of us is quite familiar with the same colour and the same diffuse fatty change in livers of patients who have died from sepsis where chloroform could not have played any part in the process. It must be admitted that in many of the recorded cases a septic cause has not been wholly excluded. Even in the case reported by Stiles and McDonald they were suspicious of a septicæmic condition, and the lungs yielded a pure culture of pneumococcus. In their further report of the case they have shown, and we think conclusively, that the pneumococcus had nothing to do with the condition. We have tried as far as possible in our case to exclude any possible septic agent. As we have already indicated, the wound was absolutely healthy; microscopic examination of the various parts of the tissues which were exposed at the operation and of the exposed bone marrow gave no histological or bacteriological evidence of local organismal infection. We attach a considerable amount of importance to the histological examination of the bone marrow of the femur, a feature to which attention has not been directed in previously reported cases. Muir and others have shown that the reaction of the bone marrow to septic infection is a very delicate one. There are very early a congestion of the vessels, an increase of the leucoblastic elements, and a disappearance of the fat cells. Carnegie Dickson[2] has shown that this congestion appears in two or three hours after infection and that the leucoblastic transformation is well marked in from 24 to 48 hours. We, of course, know that in certain very severe infections, and occasionally in the less severe, there is a leucopenia with practically no reaction in the marrow. But in such a case as we report—a young child where the bone marrow is in an actively developing condition, where there has been no long-standing disease which might cause an exhaustion of the marrow, and where no trace of bacteria could be found locally in the various organs or in the marrow—we think it extremely unlikely that it could come under this class of cases. We think, therefore, that we are justified in excluding any bacterial poison as a causal agent in this case.

Having thus excluded death from fat embolism and a poisoning by bacterial infection or by any antiseptic we feel that we are entitled to place this among that class of cases, fortunately still not numerous, where death can only be attributed to delayed chloroform poisoning. The main symptom in most recorded cases was retching and vomiting. In our case this symptom was much less prominent as the child vomited on only three occasions from the time of the operation. There had been no retching, and coffee-ground vomit was observed only six hours before death. At the necropsy a considerable quantity of a similar fluid was found in the stomach. How is this blood to be accounted for? There was no obvious lesion of the gastric mucous membrane. The bleeding may be partly accounted for by the rupture of minute over-distended capillaries, this distension being due to obstruction in the liver owing to the great swelling of the cells there. Careful examination has shown, as we have already indicated, a fatty change in the endothelium of the capillaries in various organs and this is quite well marked in the mucous membrane of the stomach. This we believe to be the main factor and the later occurrence of it in our case supports the contention that there is a rupture of the capillaries due to a fatty degeneration of their lining cells. No doubt retching would aid this rupture and in cases where there is "chloroform sickness" this coffee-ground vomit would be an earlier symptom. The coma which seems to be associated with all the cases may be accounted for in various ways. We may explain it by the formation of some poisonous products allied to acetone formed from the fat or from intermediate substances in the fat development. On the other hand, we find the destruction of almost all the secreting and excreting cells in various organs—e.g., liver, kidneys, suprarenals—and consequently there must be an accumulation in the system of the ordinary injurious products of metabolism. Added to this the fact that wasting of muscles, &c., takes place apparently in excess during the processes of fatty degeneration, we find the factors for producing an auto-intoxication.

Guthrie[3] has maintained that in these cases the chloroform has acted merely as a helper on of a pre-existing process. The very small number of deaths as compared with the number of chloroform anæsthesias gives some support to this view. Still, though we cannot disprove his contention we agree with those who maintain that the condition is a primary one and wholly due to the chloroform. It has been shown conclusively by experiments on animals that this extreme fatty degeneration can be produced in healthy organs after subcutaneous injection of chloroform or after prolonged inhalation of the drug. One of us has shown that extreme fatty degeneration in the liver and kidneys can be produced in healthy rabbits in from 24 to 26 hours after injections of bacillus diphtheriæ and we see no reason to suppose that such a protoplasmic poison as chloroform may not act as rapidly. If chloroform can produce such gross pathological lesions, lesions which are practically incompatible with life, why, it may be asked, are there so few cases of death from its action? The factor which determines that only a very small proportion of patients show these gross pathological lesions we cannot explain and we must therefore still attribute it to idiosyncrasy or susceptibility.

CONGENITAL MULTIPLE OCCLUSIONS OF THE SMALL INTESTINE.[1]

BY J. G. EMANUEL, M.D., B S., B.SC. LOND.,
M.R.C.P. LOND.,
PHYSICIAN TO OUT-PATIENTS AT THE QUEEN'S HOSPITAL AND THE CHILDREN'S HOSPITAL, BIRMINGHAM.

THE small intestine is less often the seat of congenital malformations than either the œsophagus above or the colon, the rectum, or the anus below. The commonest situations for congenital malformations in the small intestine are: (1) the duodenum at the site of the opening of the bile and the pancreatic ducts; (2) at the junction of the jejunum with the duodenum; and (3) the ileum, a short distance above the ileo-cæcal valve, at the point where the omphalo-meseraic or vitelline duct is given off. The following case is, in my opinion, unique in that the small intestine is occluded in no less than three situations, while in five other places the lumen of the bowel is practically obliterated by annular constrictions giving rise to a localised distension of the intestine immediately above, and a relative collapse below, the points of constriction.

---

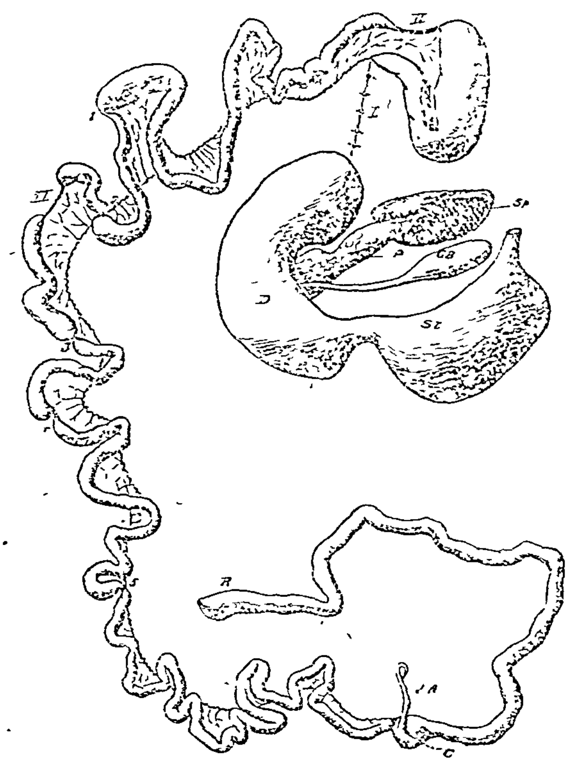
[2] W. E. Carnegie Dickson: Thesis, University of Edinburgh. (Not yet published.)

[3] Guthrie: THE LANCET, Jan. 27th, 1894, p. 193.

[1] The specimen was shown at a meeting of the Society for the Study of Disease in Children held on Jan. 20th, 1905.

This remarkable specimen was taken from an infant who was admitted into the Children's Hospital, Birmingham, under the care of Mr. C. A. Leedham-Green as a case of "imperforate anus." The child, a seven months baby, was well developed, but the skin was of a peculiar coppery hue (it looked like that of a half-Indian baby) and the nurses in the ward named the child the "bronze baby." Soon after admission to hospital an enema was given, a soft gum-elastic catheter being easily passed three or four inches up the rectum, and a large motion of meconium of normal appearance was passed. This result, of course, proved that the rectum was patent. The child had vomited all the milk that had been taken from birth. Death took place nine days after admission, operative interference being deemed inadvisable.

At the necropsy all the organs were found to be healthy with the exception of the small intestine. On opening the abdomen the most conspicuous feature was a hugely distended duodenum which was of even greater volume than the stomach. The cause of this distension was found to be a complete obliteration of the intestine at the duodeno-jejunal juncture, shown by the line -o-o-o-o- in the figure and marked I. The wall of the distended duodenum was obviously hypertrophied. The stomach wall was also hypertrophied. The pylorus was normal and the œsophagus was healthy. The stomach and the duodenum were void of contents. The first two and a half to three inches of the jejunum were distended in the peculiar manner shown in the figure and this distension was due to another obliteration of the bowel, marked II in the figure. At II the bowel was merely represented by an impervious thickening of the free edge of the mesentery half an inch in length. Still lower down in the intestine, at III in the figure, there was an exactly similar condition present—viz., a complete obliteration of the lumen, the bowel being again represented by a thickening of the free edge of the mesentery. In addition to these three situations in which the bowel was completely occluded there were five other places, 1, 2, 3, 4, and 5, in which the bowel showed annular constrictions of such completeness that *immediately above the constrictions* the intestine was distended, while below it was relatively collapsed for a short distance. The wall of the bowel in these distended parts was so thinned that the contents of the gut were visible through the wall, and these contents appeared to the naked eye to resemble ordinary meconium. Of these constrictions the most marked was that most highly situated, viz., 1, whilst the lowest, 5, was the least obvious, and, in fact, the whole series of five shows a progressively decreasing order in completeness of the constriction. The figure shows the situation of the cæcum and of the vermiform appendix and so it is clear that all these abnormalities are situate in the jejunum and perhaps in the upper part of the ileum.



A drawing reduced to exactly half size. I, II, III, Sites of occlusion. 1, 2, 3, 4, 5, Sites of constriction. St, Stomach. D, Duodenum. P, Pancreas. G B, Gall-bladder. Sp, Spleen. C, Cæcum. V A, Vermiform appendix. R, Rectum.

Some other points of interest worthy of note in connexion with this case are the following: 1. Normal meconium was passed as a result of an enema soon after the admission of the child into hospital, and yet neither bile nor any ingested products—e.g., desquamated epithelium—obtained from the amniotic fluid could have gained access to the intestine below the duodeno-jejunal juncture. This shows that, although bile and desquamated epithelium contribute normally to the formation of the meconium they are not essential and that the meconium is chiefly derived from the secretion of the alimentary canal. It may be contended that both these products had found their way into the bowel before its lumen had become obliterated; this is possible, but it must have occurred very early in intra-uterine life, because the occlusions at II and III must be of very early formation, if, indeed, the intestine was pervious from end to end at any date. In connexion with the part played by the bile in the formation of the meconium it may be borne in mind that in cases of congenital obliteration of the bile ducts it is the rule for normal meconium to be passed soon after birth but for all subsequent motions to be devoid of bile pigment.[2] Foster speaks of a considerable quantity of meconium being found in the fœtus in cases where the liver has been absent.[3] 2. With so complete an obstruction as occurs at the duodeno-jejunal juncture one might have expected to find the bowel below in a state of collapse and yet instead of this we find that immediately above the occluded parts II and III and the constrictions 1 to 5 the bowel is actively distended with what appeared to be ordinary meconium. It is clear that the whole of the meconium within the jejunum, the ileum, and the colon must have been secreted from the glands in the intestinal walls and that this secretion is capable of going on in a segment of intestine completely cut off above and below—e.g., in the segment between I and II, and that between II and III. 3. Nine days is a long time for an infant—especially a premature infant of seven months—to survive without any food.

Congenital malformations are generally said to be either the result of an intra-uterine peritonitis giving rise to bands of adhesion which cause strangulation, or to be due to an arrest of development. In the present case there were no signs of any peritonitis, either recent or old, and so we are led to adopt the second somewhat unsatisfactory theory and say that the anomalies described above are due to an arrest of development. It seems to me, however, that rather than being due to an arrest of development these abnormalities are due to an accident in the course of development of the nature of strangulation and that two stages may be distinguished in the process—viz., a strangulation at the duodeno-jejunal juncture during the formation of the duodenal loop and later the formation of a number of more or less complete volvuli during the process of lengthening of the intestine and the formation of its coils. It will be remembered that the duodeno-jejunal juncture is the most fixed portion of the small intestine, being held in position by the superior mesenteric vessels which groove its anterior surface and by a strong fibrous band descending from the left crus of the diaphragm and the tissue round the cœliac axis. This band, better marked in the fœtus and young child than in the adult, contains plain muscular fibres and is called the musculus suspensorius duodeni.[4] This, moreover, is the point where the gut first receives a full investment of the peritoneum. The duodenal loop is formed by the twisting of the embryonic stomach, which early occupies a median position with its surfaces right and left, its greater curvature posterior and its lesser curvature anterior. The pyloric end becomes tilted away from the vertebral column in such a way that the right side of the stomach becomes its posterior surface and the duodenal loop is thrown over to the right side of the abdomen. This duodeno-jejunal juncture is therefore a very likely place for an intra-uterine obstruction to occur, and statistics, in fact, support this view, for it is the second situation in point of frequency for congenital malformations of the small intestine to occur. If, then, we grant that this was the main obstruction it is fair to conclude that later in intra-uterine life when the small intestine, originally short and straight, lengthened and became thrown into coils it underwent an amount of twisting with the production of a number of volvuli of more or less complete formation and that this twisting gave rise to the complete occlusions II and III, as well as to the constrictions 1 to 5. In support of this view it is to be remembered that in these two situations the thickened free margin of the mesentery represents the intestine—i.e., the intestine is not completely obliterated but is represented by impervious fibrous cords, the free margin of the mesentery.

[3] Foster, Text book of Physiology, vol. iv., p. 1527.

[4] Quain's Anatomy, vol. iii., Part iv., p. 102.

I have not been able to find records of a case similar to the above. Hirschsprung of Copenhagen in a thesis on congenital occlusions of the small intestine, of which an epitome is to be found in the *Medico-Chirurgical Review* for 1862, collected records of 31 cases. Of these, in 16 (more than 50 per cent.) the lesion was situate in the duodenum; in six in the ileum close to the cæcum, and therefore probably connected with the omphalo-meseraic or vitelline duct; and in nine cases the lesion was situate in intervening portions of the gut. In no instance, however, was the abnormality repeated in the course of the canal and it is in the multiplicity of the occlusions that the present case differs from those in the above series.

In conclusion, I would express my thanks to Dr. A. E. R. Weaver, the resident medical officer of the Children's Hospital, Birmingham, for his excellent drawing of the specimen, and to Mr. Leedham-Green for his courtesy in allowing me to publish this case.

Birmingham.

A CASE OF SACCULATED ANEURYSM OF THE ABDOMINAL AORTA, TREATED BY THE INTRODUCTION OF SILVER WIRE AND THE PASSAGE OF CONSTANT CURRENT:

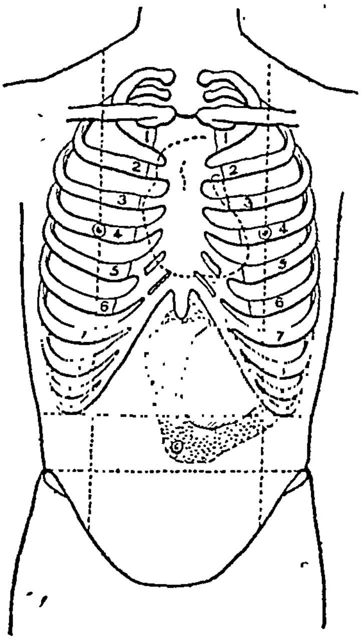
WITH DESCRIPTION OF A SIMPLE METHOD OF INTRODUCING THE WIRE AND INSULATING THE CURRENT.

BY CORNELIUS A. GRIFFITHS, F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE CARDIFF INFIRMARY.

THE patient, a male, aged 37 years, was admitted to the Cardiff Infirmary on July 1st, 1904, complaining of a lump in the epigastric region; with continuous pain in the left side and pain of an acute boring character in the back. Stated very briefly his history was as follows. By profession he was a travelling photographer and he dated his illness back to a day about two months previously when lifting the bag containing his rather heavy camera and other impedimenta, and giving it a swing over his shoulder, he first noticed pain in his back which he attributed to a strain, because he lifted the case rather more jerkily than usual—being in a hurry on that occasion. He had always been a temperate man. No history of syphilis could be obtained, but he had a gonorrhœa some 20 years ago; there was no history of rheumatism.

On admission the patient presented the appearance of a man suffering from continual pain. The tumour in the abdomen occupied mainly the epigastric region and was almost entirely on the left of the middle line; it became lost under the ribs and extended downwards nearly to the umbilicus, its size being about that of a cocoanut; it caused some bulging of the epigastrium and was distinctly a pulsating tumour with a well-marked systolic bruit; in short, no doubt was entertained as to the aneurysmal nature of the tumour, and the diagnosis was that of a sacculated tumour of the commencement of the abdominal aorta (*Fig.* 1). Pain was complained of in the back and on the left side and this was said to be constant; pain in the epigastrium also followed the taking of food and there had been occasional retching but no actual vomiting. The pain in the back was the most complained of and was bad enough to keep him awake at night. The patient was an intelligent man and said that there had been no increase in the size of the tumour lately, but he thought it had become harder and although at one time he was able to "squeeze it all away" he was now unable to do so. Pain was also complained of in both legs below the knees but not in the thighs or the lower abdomen. The heart sounds were clear, the pulse was regular, tension fairly high, with a suspicion of thickening of the arteries. There was no evidence of any other aneurysm. There was no albuminuria.

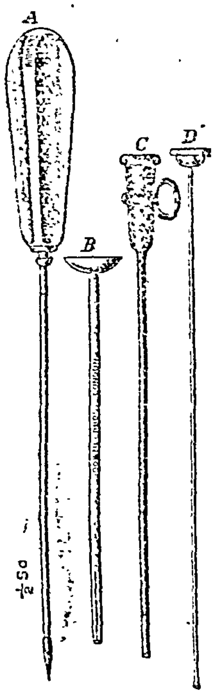
FIG. 1.



The lined area is that of the evident tumour; the dotted area is that of comparative dulness round the tumour merging above and to the right in the dulness of the liver.

Operation was performed on August 3rd, 1904. The usual preparations for carrying out an aseptic operation were made and the patient was anæsthetised by Dr. Cyril Lewis, ethyl chloride and ether being used. An incision a little to the left of the middle line was made over the tumour and the abdomen was opened, the aneurysm presenting immediately below the diaphragm and above the lesser curvature of the stomach, the viscus being closely applied to, and stretched around, the left and lower borders of the aneurysm. I had intended, if possible, placing a temporary ligature around the aorta on the proximal side of the tumour, but this was not practicable, as the sac left no room between its walls and the diaphragm. A spot devoid of large vessels was now selected on the surface of the tumour and a small circle inclosed in a purse-string suture, and through the centre of this a fine long metal trocar and cannula were thrust well into the sac. The trocar was withdrawn, the cannula remaining in position, and through this was introduced a vulcanite cannula for insulating purposes. Next some fine silver wire was introduced into the sac through the double cannula. While putting in the wire I tried to avoid the communication between sac and aorta by keeping the end of the cannula directed to one or other side of the sac, with what success will appear later. After a foot or so of wire was in the wire "kinked," so it was cut off flush with the cannula and pushed home with the ramrod which I had specially prepared with a "cupped" end for this purpose and found that it worked very satisfactorily. Some more wire was then pushed through and connected with the negative terminal of a constant current battery, the circuit being completed through the patient by means of an electrode placed on the thorax. A current of from 15 to 25 milliampères was given and continued

FIG. 2.



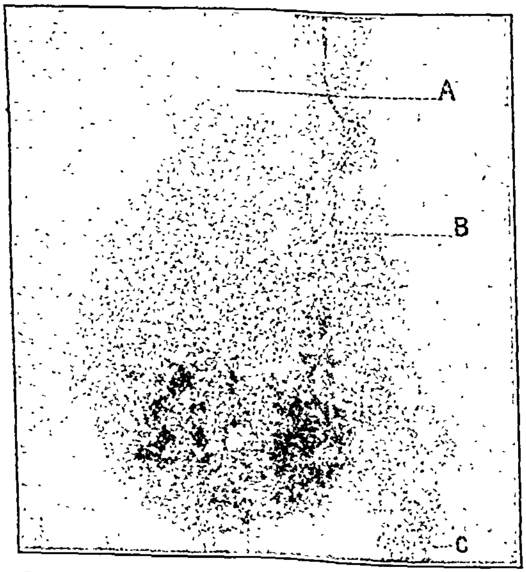
A, Metal trocar. B, Metal cannula. C, Vulcanite cannula. D, Ramrod.

for 15 minutes; at the end of this time it was noticed that the aneurysm felt harder and the expansile pulsation had grown less if it had not quite disappeared. The wire (about six feet) was then pushed home with the ramrod, the cannulæ were withdrawn, the purse-string suture was tied, and the abdomen was closed. It was noticed after the abdomen was closed that the bulging caused by the tumour had almost disappeared. The patient suffered greatly from shock and although consciousness was recovered restlessness was very marked, the patient throwing himself about and exhausting what little pulse remained and he died five and a half hours after operation.

The post-mortem examination showed that there had been no hæmorrhage. The heart was healthy; the arch of the aorta showed signs of atheromatous changes. The aneurysm came off from the main trunk of the abdominal aorta and communicated with it by means of a narrow elongated mouth about one and a half inches in length. The sac was filled with a dark clot and coiled wire, a double loop of which had entered the aorta and passed for about two and a half inches up into the thoracic aorta. I have taken a radiograph of the aneurysm and adjoining parts of the aorta exactly as removed from the body in order to show (Fig. 3) the disposition of the wire in the sac and its passage into the aorta. There was no erosion of the vertebræ.

This is at present the only case of aneurysm of a large vessel in which I have had an opportunity of trying the wire and electrolysis method and at first sight it does not seem encouraging, but the cases reported by Maunsell,[1] H. A. Ballance,[2] and others lead one to hope that the cure of these distressing cases is becoming surgically possible, hence I record this case hoping that some of its points may prove useful.

FIG. 3.



In the radiograph A marks the level of the diaphragm, the thoracic aorta appearing above. B marks the wire coiled in the aneurysm. C, Continuation of the abdominal aorta.

For carrying out my wishes in the preparation of the very simple instruments (Fig. 2) used during the introduction of the wire I am indebted to Messrs. Down Brothers. In actual practice I found the instrument work quite easily, the "cupping" at the end of the ramrod engaging the end of the wire and running it down the cannula without trouble. I was agreeably surprised to find that there was practically no hæmorrhage from the sac on introduction of the trocar and although a slight trickle took place at the side of the cannula while the wire was being introduced it stopped soon after the electric current was turned on.

That the passage of the wire into the trunk of the main vessel is a point to be reckoned with is apparent on a glance at my radiograph. I certainly tried to prevent this by the position of the mouth of the cannula but unsuccessfully; it will be observed that it was a double loop of wire and not the ends of wire which escaped. Perhaps if one used short lengths of wire this might not happen. The immediate clotting within the sac by the passage of a small current I think is a distinct gain.

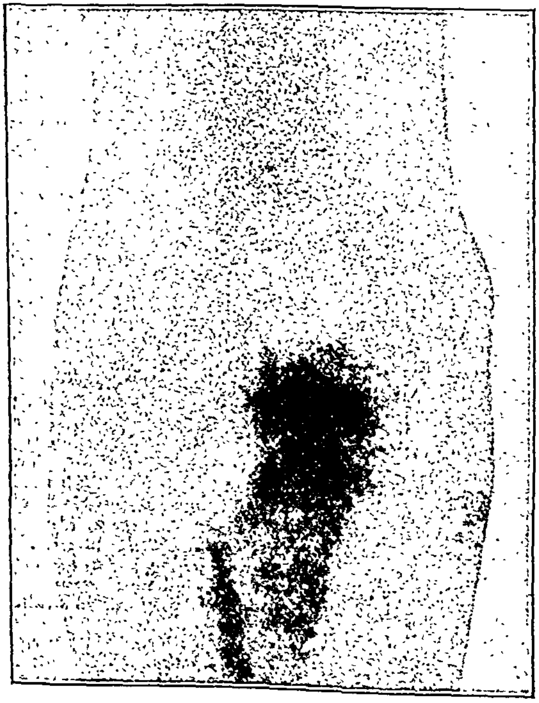
The rapidly fatal termination in my case, I have no doubt, was favoured by the interference with the functions of the stomach, which, as I have already stated, was stretched around the left and lower borders of the aneurysm. The patient failed rapidly before the operation and became increasingly anxious that something should be tried to relieve him even if it were not successful. Iodide of potassium was administered on admission, five-grain doses increasing to 15 grains three times daily, and for a couple of weeks before the operation the patient received ten grains of calcium chloride night and morning.

Cardiff.

FRACTURE OF THE HEAD OF THE RADIUS.

BY ROBERT KNOX, M.D. EDIN., M.R.C.S. ENG., L.R.C.P. LOND.

THE accompanying skiagram illustrates a form of fracture which is not frequently met with. The patient, a man, aged about 30 years, was thrown from a carriage and was found to have injured his elbow-joint. When I saw him the exact



Skiagram showing fractured head of radius.

---

[1] Brit. Med. Jour., June 18th, 1904.
[2] THE LANCET, Oct. 1st, 1904, p. 939.

nature of the injury could not be made out on account of the extensive swelling which occurred immediately after the injury. There were immobility of the joint and widening in the transverse diameter, and on movement of the joint crepitus could be elicited. Skiagrams revealed the exact nature of the injury—namely, fracture of the head of the radius with displacement of the upper fragment backwards and outwards. The joint after four weeks was rigidly fixed and movements were found to be impossible. The patient was anæsthetised and the joint was forcibly extended and flexed. Crepitus could still be elicited. An attempt was made to bring the fragments into exact apposition but this was found to be impossible. The arm was put up in a right-angled splint and kept quiet for a few days until the swelling had subsided, then early passive movements were commenced. These movements were continued twice daily for a fortnight and afterwards continued along with massage of the muscles. Later pronation and supination of the forearm were commenced and continued for several weeks. When I last saw the patient three months afterwards he had recovered a considerable amount of extension and flexion; he could pronate and supinate the forearm perfectly. The joint appeared to be normal and the fracture had united. The movements of flexion and extension were limited slightly. The patient had a useful arm and judging from the progress made in the short time he was under treatment I hoped he would ultimately recover the full use of the joint.

The case illustrates the difficulty of diagnosing injuries of the elbow-joint and shows the great value of the Roentgen rays in cases of injuries of joints where the nature of the lesion cannot be exactly determined.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE, W.C.

A CASE OF SYPHILITIC INTRACRANIAL DISEASE.

(Under the care of Dr. THOMAS BUZZARD.)

FOR the notes of the case we are indebted to Dr. F. L. Golla, resident medical officer.

A man, aged 29 years, was sent by Dr. W. M. G. Glanville to the National Hospital for the Paralysed and Epileptic and admitted under the care of Dr. Buzzard on May 31st, 1905, complaining of loss of power in the left arm, headaches, and outbursts of laughter. He had served as a soldier in India and contracted syphilis four years ago; he was treated for three weeks by mercurial injections. He had a secondary rash but no other symptoms. Up to two months previously to admission he was feeling perfectly well but then developed right facial neuralgia which was ascribed to bad teeth. A tooth was extracted without any relief. A month later he began to suffer from severe headaches of frontal character. At the same time the neuralgic pains began to disappear. A week previously to admission he lost power in the left arm, which felt numb and useless. The loss of power was not complete. The acute loss of power lasted for two days and then began to improve. The sensation of numbness also gradually diminished. About five days previously to admission he became aware of facial palsy and suffered from uncontrollable outbursts of laughter and weeping. He had no vomiting or difficulty in swallowing. He noticed slight deafness of the left ear.

On admission the patient, a well-developed young man, looked extremely ill and was drowsy and apathetic. The pulse was full, with a tension of 160 millimetres of mercury, and very slow, averaging about 40 beats per minute. With regard to the cranial nerves, there was some degree of hyperæmia of the right optic disc but no definite swelling. The pupils reacted normally and all ocular movements were normally performed. There was no nystagmus or diplopia. There was slight nerve deafness of the left ear. There was definite weakness of the lower left facial muscles both to voluntary movements and in a lesser degree to emotional movements. He was liable to spasmodic attacks of laughter or weeping, during which all the facial muscles were uniformly affected; there was no corresponding involvement of the laryngeal muscles during these attacks, which were noiseless, but accompanied by lacrymation. All the other cranial nerves were normal. Smell was unimpaired. There was some definite weakness of the left arm, especially in the movements of the distal joints, and very slight relative weakness of the left leg was present. There was no objective sensory abnormality and stereognosis was unimpaired. The deep reflexes were much diminished on either side; the knee-jerks could only be obtained on reinforcement. The superficial reflexes were brisk and equal. The left plantar response was extensor and the right was flexor.

A tumour of the right temporo-sphenoidal lobe was diagnosed on admission. Three days after admission there was complete absence of all deep reflexes. Four days after admission the patient was considerably worse. He was very drowsy and vomited frequently. He could only be induced to take food with difficulty. He would only answer in monosyllables when addressed. He still had frequent attacks of laughter and weeping. The pulse was 38 and the blood pressure measured by the Riva-Rocci apparatus was 165 millimetres of mercury. Breathing was occasionally somewhat irregular and his condition was generally so alarming that Dr. Buzzard was telephoned for. The patient was ordered inunctions of one drachm of unguentum hydrargyri twice a day and 15 grains of potassium iodide every four hours and free purgation with calomel. Three days later the patient showed signs of commencing salivation and the mercury was discontinued. Four days after the commencement of mercurial treatment the patient showed considerable improvement. He was less drowsy, the pulse was about 60, and the blood pressure sank to 135 millimetres of mercury. A week after the onset of the antisyphilitic treatment the spasmodic laughter had nearly disappeared and there was no trace of the left-sided weakness beyond a relative weakness of the grasp of the left hand when compared with the right. The hyperæmia of the right disc was, if anything, less pronounced. The deep reflexes still remained absent and the left plantar response extensor. The headaches and vomiting had completely vanished. The potassium iodide was now diminished to 30 grains three times a day. A month after admission the patient was discharged as cured. The only signs of his recent illness were the absence of the deep reflexes (the knee-jerks could be only obtained on reinforcement) and slight deafness of the left ear. Both plantar responses were flexor.

Remarks by Dr. BUZZARD.—The symptoms of intracranial tumour in this case were well marked and shortly after admission became so alarming (although the patient was under specific treatment) that the question of operative interference had to be seriously considered. But in view of the history of syphilis and the patient's age and the strong probability that the symptoms were due to the presence of gumma or gummatous meningitis of the right cerebral hemisphere it was resolved to persevere in the specific treatment and this was accordingly at once very actively pushed. The result was eminently satisfactory.

LEEDS GENERAL INFIRMARY.

A SERIES OF CASES OF TOOTH PLATE IMPACTED IN THE ŒSOPHAGUS; REMOVAL IN ONE CASE BY LATERAL ŒSOPHAGOTOMY.

(Under the care of Mr. H. LITTLEWOOD.)

FOR the notes of the cases we are indebted to Mr. H. Collinson, late resident surgical officer.

CASE 1.—This patient, the most interesting of the four, was a man, aged 35 years, who was admitted to the Leeds General Infirmary on March 23rd, 1902, with the following history. During the night of Feb. 14th he awoke suddenly and discovered that he had in his sleep swallowed a tooth plate containing three teeth of the upper jaw. At this time he experienced no great pain and stated that by putting his finger down his throat he could reach the plate. He went to a druggist in the early hours of the morning and an emetic was administered but the plate could not be dislodged. Shortly afterwards the plate slipped further down the gullet and began to cause him great pain; he then with difficulty walked to the local hospital suffering agony at every respiration. He remained in the hospital for some weeks and during this time several unsuccessful attempts at removal were made, both with and without anæsthesia. Early in March he commenced to suffer from severe cough with foul expectoration and his breath became extremely offensive. On March 23rd he was admitted to the infirmary complaining of slight difficulty in swallowing solid food and the expectoration of large quantities of fœtid pus. From these symptoms it was inferred that the tooth plate had ulcerated through the œsophageal wall and opened the left bronchus or one of the larger bronchial tubes and was lying partly in the œsophagus and partly in a bronchiectatic cavity. A skiagram demonstrated the presence of the foreign body at the level of the fifth dorsal spine.

On April 3rd—i.e., seven weeks after the accident—Mr. Littlewood operated under ether anæsthesia. An incision was made along the anterior border of the left sterno-mastoid commencing at the clavicle, the edge of the muscle was demonstrated, and the omohyoid, sterno-hyoid, and sterno-thyroid muscles were divided. The left lobe of the thyroid gland, which was found to be enlarged and cystic, was removed and the œsophagus was exposed; this was then opened by an incision one and a half inches in length and the edges of the wound were held apart by small volsella. A coin-catcher was passed and after some difficulty the edge of the tooth plate was located apparently projecting into the left side of the œsophagus. After repeated attempts with a pair of long œsophageal forceps the edge was at last caught and the plate was dragged out. It was covered with exceedingly foul pus and had evidently lain imbedded in the wall of the œsophagus and an abscess cavity communicating with the left bronchus. The œsophageal incision was closed by a continuous catgut stitch and the external wound wae partially sutured and drained; there was some subsequent suppuration about the wound but it was quite healed in a month. The present condition of the patient is, on the whole, satisfactory; he still expectorates a quantity of purulent sputum which, however, is not offensive, and examination of the chest reveals occasional râles at the left apex but the signs are insignificant.

The next three cases bear a striking resemblance to the foregoing so far as their history is concerned; all swallowed the tooth plate whilst asleep; in one the plate carried four and in the other two cases three upper teeth.

CASE 2.—A man was admitted to the Leeds General Infirmary on June 16th, 1903, having swallowed his tooth plate the previous night. He presented no symptoms. A skiagram demonstrated the plate at the level of the fourth dorsal spine. Under ether it was removed with the coin-catcher after one or two attempts. The patient left the hospital on the next day.

CASE 3.—This patient was admitted to the Leeds General Infirmary on June 3rd, 1904, with an identical history. After a skiagram had been taken showing the plate at the level of the second dorsal vertebra the foreign body was removed without difficulty with the coin-catcher.

CASE 4.—A man was admitted to the Leeds General Infirmary on August 6th, 1904, stating that he had swallowed a tooth plate ten weeks before. He had spent three weeks in the local hospital, where unsuccessful attempts had been made at removal. No successful skiagram had been taken. On admission he complained of pain at the level of the cricoid cartilage and difficulty in swallowing with occasional vomiting. A skiagram showed the foreign body at the level of the fourth dorsal vertebra. On August 8th it was removed with the coin-catcher at the third attempt. The patient left the hospital on the next day.

Remarks by MR. COLLINSON.—The impaction of a foreign body in the œsophagus is by no means an uncommon accident in children and in the greater number of cases the impacted body is a coin—usually a halfpenny. Its removal by means of a coin-catcher even at a considerable interval of time after the accident is usually a comparatively easy matter and it is rarely that an anæsthetic is necessary. In adults accidents of this nature are less common and the impacted body is usually larger—most frequently a tooth plate—and its removal is a more formidable undertaking. The above series of cases occurred within a comparatively short space of time and were all admitted to the General Infirmary at Leeds under the care of Mr. Littlewood, by whose courtesy I am permitted to record them.

As regards Case 4, an impaction of ten weeks' duration had apparently led to little, if any, damage to the œsophageal walls and the removal proved to be comparatively simple, but when one compares Case 1, in which the impaction was of shorter duration, one realises the dangers which are liable to accrue from the presence of a large and irregularly shaped foreign body in the œsophagus. A cross-section of the thorax at the level of the fifth dorsal vertebra shows that the relation of the œsophagus to the descending aorta is almost as close as its relation to the left bronchus and although the arterial walls are doubtless more resistant than those of the bronchus, cases have not infrequently been reported in which foreign bodies have produced a fatal result from ulceration of the former. The removal of a foreign body the impaction of which is of long duration is therefore an anxious operation to all concerned and one in which the greatest care is essential. The cases recorded illustrate the danger of sleeping with small tooth plates in the mouth, particularly if they do not fit well, and also the great value of the x rays in their localisation when accidentally swallowed.

On reference to the literature it is found that Eitel reports a case of lateral œsophagotomy for the removal of a tooth plate six years and four months after the accident, and Maylard reports a case for Lennox Browne in which a tooth plate was successfully removed with the coin-catcher after the lapse of three and a half years, but there are evidently only a few cases in which a tooth plate which has produced the grave lesion that occurred in Case 1 has been successfully removed by lateral œsophagotomy.

Medical Societies.

BRITISH ELECTRO-THERAPEUTIC SOCIETY.—A provincial meeting of this society was held at Leicester on July 26th, Dr. Donald Baynes, the President, being in the chair.—Dr. H. Lewis Jones opened a discussion on the Present Position of the Treatment of Carcinoma and Sarcoma by Electrical Methods, illustrating his remarks with two cases which he brought from London.—Mr. T. J. Bokenham then gave an address on the Treatment of Stricture of the Urethra by Electrolysis, showing some new forms of instruments for this purp —The meeting then adjourned to July 27th, Mr. J. Hall-Edwards read a paper on X Ray titis, showing various protective devices, including and improved tube shield designed by Dr. Belob of Dr. E. R. Morton, the secretary, on behalf of Mr. Chislehurst, showed a Tooth-brush extracted b from the stomach of a patient 50 hours after swallowed during a fit of temporary insanity suicide. The action of the gastric juice on the brush was most remarkable. The accompanied the specimen showed it stomach very satisfactorily.—Dr. G. paper on Æsculin in Conjunction with Treatment of Lupus Vulgaris.—Dr. paper on the Diagnosis of Early Tu X Ray Examination of the Chest. a very interesting series of la patients whom he had had ur then adjourned until July 28t cribed and showed a new co quency Couch which was very from complication. It was f present.—Dr. Lewis Jones rea the Milliampèremeter as a M illustrated by a series of lan opened a discussion on the Inf on Blood Pressure and Body T those present took part.—The on Neurasthenia.

EXETER BOROUGH AS annual report of the Exeter just been issued, states that t institution on Dec. 31st, 1904, males and 190 were females.

different species of the same class. The probable modes of infection are by the accidental inoculation of material containing the parasites or possibly through a biting insect. Again, the evidence adduced points to the fact that even when numerous parasites are found in a Delhi sore no general disease such as kala-azar results, hence it is not likely that the infection occurs by the skin in kala-azar; also if any biting insect were proved to be the infecting medium of the sores it would not follow that kala-azar could be contracted in this way. Lastly, as the parasites were found in oriental sores contracted in Delhi, Kurnaul, Shahabad, Lahore, Quetta, and Dera Ismail Khan we may conclude that the sores known as "Delhi," "Lahore," "Sind," and "frontier" sores are one and the same disease caused by the same parasite. The ulcers known as "Naga sores" are apparently of a different nature.

The author has not found any confirmation of the opinion that true Delhi sores occur in dogs and other animals. He failed to communicate the affection to the former. Lastly, he investigated the question of the parasite acting as a cause of enlargement of the spleen. There is a close resemblance between the parasites of Delhi sore and those found in certain cases of enlargement of the spleen. Captain James concludes with regard to this that it is not justifiable to hold all the cases diagnosed as "malarial cachexia with enlargement of the spleen" as being due to the parasite recently discovered in the spleen and other organs, but that a diagnosis of "malarial cachexia" would in all probability in the present state of our knowledge be correct. The work is illustrated by an excellent plate of the micro-organism and altogether reflects great credit on the author.

Mammalian Anatomy, with Special Reference to the Cat. By ALVIN DAVISON, Ph.D. London: Rebman, Limited. 1903. Pp. 250, with 108 figures in the text. Price 7*s.* net.

THIS small treatise is not at all modeled upon the two best-known works dealing with the cat and its anatomy. The classical handbook of Strauss Durckheim is mainly admirable nowadays on account of its fine engravings of the osseous and muscular systems, while Dr. Mivart's, "The Cat," is anything and everything about the cat, psychological as well as anatomical and physiological. The author of the modest introductory work before us contents himself with a general survey of feline structure in as few words as possible and with as many illustrations as are needed to save verbiage. Accompanied by this text-book it will be easy to ascertain for oneself by dissection the principal features in the anatomy of a cat, or, indeed, of most mammals. Histology, where absolutely necessary—as, for instance, in the case of ovary and ova—is not neglected and it is remarkable into how small a space Dr. Davison has been able to compress most of the essentials. We are obliged to say "most" of the essentials, since there is no disquisition upon the cœlom. This word, "body cavity," and "diaphragm" do not occur in the index, though there is some account of the mesenteries which suspend the viscera and the diaphragm is figured. The cœlom ought to have had a section to itself, duly set forth in the table of contents, inasmuch as the modification of that organ is one of the most typical features of mammalian anatomy as compared with that of lower vertebrates. In no vertebrate that is not a mammal and in all mammals without exception is the cœlom divided into two chambers—a thoracic and an abdominal—by a muscular partition lying behind the lungs but in front of the liver. Otherwise, there is hardly an anatomical question raised by the actual facts that is not referred to. The rigorous saving of space has, however, compelled the author to deal with many topics in what the Germans call a "step-motherly" fashion. The functions of such organs as the thyroid are merely hinted at and such histology as is considered necessary to the book is summarily dealt with. The numerous figures add greatly to the usefulness of the book, especially those that are anatomical; the histological drawings are largely from micro-photographs and for the most part do not strike us as being thoroughly satisfactory. A section, for example, of intestine on p. 131 is more like a drawing of the horn of a rhinoceros than anything else in nature.

LIBRARY TABLE.

Die Chirurgischen Eingriffe bei Storungen des Bewegungs-Apparates der Augen. (The Surgical Treatment of Muscular Defects of the Eyes.) By Dr. E. LANDOLT of Paris.—In this pamphlet Dr. Landolt recognises two modes of operative procedure for the cure of strabismus—tenotomy and advancement; tenotomy being the division of the tendon of the muscle which appears to be acting too strongly and advancement being the bringing forward, either with or without division, of the muscle which appears to be inefficient, and by this means affording it a better purchase to effect the rotation of the eye. Both proceedings, tenotomy and advancement, may be practised simultaneously or successively. In each case the excursion of the eye, the capability of convergence, and the power of single vision with the two eyes must be tested before and after the operation. Dr. Landolt describes the different modes of performing tenotomy and dwells upon the ill consequences that are so often observed even when this operation has been cleverly done. He points out the many advantages that result from advancement, though he acknowledges that it requires much more care and skill than simple tenotomy. He gives full details of the plan which he has himself, after much consideration, adopted and supplies a drawing that elucidates the somewhat complicated proceedings. In regard to the etiology of squint, he regards strabismus convergens as due to spasm of convergence—that is, of one or both of the internal recti—brought about by hypermetropia, as Donders maintained. It is active in its nature. Strabismus concomitans divergens, on the other hand, is due to relaxation of convergence and is a passive condition. An appendix contains a simple mode of enucleation, the chief feature being the employment of a pair of scissors curved both on the flat and on the edge. There is a very complete bibliography of the operations that have been proposed or adopted for squint.

Indigestion Clearly Explained, Treated and Dieted, with special remarks on Corpulency, Gout, and Constipation. By THOMAS DUTTON, M.D. Durh. Sixth edition, enlarged and revised. London: Henry Kimpton. 1905. Pp. 212. Price 1*s.* 6*d.* net.—The sixth edition of this work is published at a reduced price. The author says that he is totally averse to the members of the medical profession advertising themselves in any way but is in favour of the profession educating the public up to the times by means of medical works—such works as the general public can be trusted safely with, which will lead them away from the path of quackery.

The Seaside and Inland ABC Holiday Guide to all Health and Pleasure Resorts and Places of Interest in the United Kingdom. Illustrated with photo views. London: Wentworth Publishing Company. 1905. Pp. 331. Price 1s. net.—The aim of these pages is to give in a concise manner accurate and plain descriptions of all recognised resorts and places of interest in England, Scotland, Ireland, and Wales, with such particulars as to situation, access, population, and distance as may be useful to the prospective visitor and which may enable him to form an idea as to what each place is like. The younger generations will here see places described which cater for their amusement and entertainment; the older folk, the feeble and the afflicted, may read of quiet places of retreat where they may find renewed life and vigour. A list of the golf links throughout the kingdom is to be found at the end of the work, together with lists of all the principal angling stations, of the mountain districts, and of the coaching centres. This little guide appears to us to be all that the publishers claim for it; wherever we have dipped into its pages we have found the information accurate and the descriptions just and fair.

How to Become a Nurse: The Nursing Profession, How and Where to Train. Edited by Sir HENRY BURDETT, K.C.B. New and revised edition. London: The Scientific Press, Limited. 1905. Pp. 360. Price 2*s.* net.—This is the seventh edition of this book from which full particulars can be obtained concerning the nurse training schools in this country, the colonies, and the United States of America. The contents of the book are official in that they are revised each year by the representatives of each institution. The text has been somewhat added to in this new edition. The work certainly fulfils the two chief purposes for which it was designed. In the first place it meets the case of every woman who is attracted to nursing and desires to become a fully trained nurse, and in the second place it has proved of material assistance to matrons and hospital officials in lessening the amount of correspondence by inquirers who seek the information which it contains. The particulars in the volume are arranged on a uniform plan which makes reference easy. The book begins with a useful summary of some of the requirements of the training schools and this will simplify matters for those who are thinking of taking up nursing as a calling. The aim of the editor is to give such an account of the requirements which may have to be fulfilled that each reader before taking up the work of nursing may have some knowledge of what qualifications and so on are essential and what the duties will generally be. A useful and very clear outline of the principal laws affecting nurses is contained in a chapter of 13 pages. The final pages are devoted to a consideration of the provident funds and associations for the benefit of nurses.

Garden Cities in Theory and Practice. By A. R. SENNETT, Member of the Institute of Civil Engineers. London: Bemrose and Sons, Limited. 1905. 2 vols. Pp. 1404. Price 21*s.* net.—This work is an amplification of a paper on the Potentialities of Applied Science in a Garden City which was read before Section F of the British Association for the Advancement of Science. Mr. Sennett, who is well known in the different sections of the engineering world as the author of kindred works and as the honorary librarian of the Automobile Club, is as well qualified as one man can be to write on the great number of questions of which these thick volumes treat. In his introduction he ventures the opinion that in his "Garden Cities of To-morrow" Mr. Ebenezer Howard has produced a book which, aided by the support of public opinion, may promote a great and beneficent change and open up a new vista in social, industrial, and national welfare. Mr. Sennett writes: "I do not know that any apology is due from me for a work upon the same subject, seeing that it is put forward in reinforcement of that to which I refer, except it be for its length, which has arisen from anxiety on my part to bring forward matters for consideration during the inception of the proposed cities." In turning over the pages of these beautifully illustrated volumes we are transported to the realms of the author's Utopia, and while we write "of the author's Utopia" we are conscious that it is one which is, in part at least, capable of realisation if those responsible will only remember the words of Lord Chesterfield that "those who aim vigorously at perfection will come nearer to it than those whose laziness or despondency makes them to give up its pursuit from the feeling of its being unattainable." Mr. Sennett says that in these pages he has ventured to assert that the day for the useful discussion of the industrial economics of a nation is passed and become next to valueless. For no scheme, thesis, or principle can be of utility or practically workable which is not founded upon a basis formed from the data derived from subsisting international conditions. "If we are to retrieve our supremacy, or, indeed, to re-establish ourselves upon a firm commercial basis, are to build new and improved cities in which capital can be invested and safely and profitably worked, we must learn to think both imperially and internationally. We must, moreover, be prepared to conform to such changes—be they industrial, social, commercial, or fiscal—as time has wrought; changes to which others, less self-satisfied but of greater prescience, have already found it beneficial to conform." Mr. Sennett's suggestions are strenuous and exhilarating; they must help to solve a gigantic problem, to neutralise the evil effects of overgrown populations, and thereby to increase the social happiness of the masses in this country.

JOURNALS AND MAGAZINES.

The Journal of Physiology. Edited by Sir MICHAEL FOSTER, K.C.B., F.R.S., and J. N. LANGLEY, Sc.D., F.R.S. Vol. XXXII., Nos. 5 and 6. July 13th, 1905. London: C. F. Clay. Price 11*s.*—The contents of these numbers are as follows:—1. On the Chemical Specificity of Precipitins, by Andrew Hunter, M.B., chemical research scholar. Precipitins are antibodies and were first discovered by Bordet in 1897. He treated rabbits with repeated injections of cow's milk and found that in time the serum of the animal treated gained the property of precipitating milk even in extreme dilution. Similar precipitins were subsequently obtained by injections of blood sera, white of egg, hæmoglobin, and many other proteids. Wassermann demonstrated the specific nature of this reaction. The serum obtained by injection of, say, ox serum would precipitate the serum of an ox but within limitations no other serum, not the serum of the horse or of the dog or of the guinea-pig. Later researches have shown that there is some, though not a powerful, action on the serum of nearly related animals. Dr. Hunter shows that the albumin, euglobulin and pseudo-globulin of ox serum are each capable of leading to the formation of precipitins which are in a limited degree specific. The precipitins thus obtained are mixtures of at least four distinct antibodies, of which albumin yields one only, while euglobulin and pseudo-globulin each yield three. The production of precipitins follows a wave-like course and is concurrent with an intermittent leucocytosis, the number of leucocytes at any moment bearing an inverse relation to the amount of precipitin. 2. Observations on the Gaseous Metabolism of the Small Intestine of the Rabbit, by A. E. Boycott, M.D. Oxon. In these experiments it was found that oxygen disappears from the intestine partly by diffusion but mainly by being changed or absorbed by the mucous membrane. It is normally present in the intestine of the rabbit. The intestinal wall is very permeable by carbon dioxide. Nitrogen injected into the intestine undergoes little change in five hours. There are certain combustible intestinal gases which are complex and of unknown proportions. 3. Of the Efferent Relationship of the Optic Thalamus and Deiter's Nucleus to the Spinal Cord, with special reference to the Cerebellar Influx of Hughlings Jackson and the Genesis of the Decerebrate Rigidity of Ord and Sherrington, by F. H. Thiele, M.D. Lond., pathologist to University College Hospital. Dr. Thiele's experiments show amongst other points that the optic thalamus contains in its posterior part on each side a centre which controls the coördinated movements of walking; that the optic thalamus exerts an inhibitory control over the opposite cortical cells; and that the cerebellar cortical cells appear to exert an inhibitory action over Deiter's nucleus of both sides but especially of their own side. 4. The Changes in the Viscosity of the Blood during Narcosis, by R. Burton-Opitz, from the Physiological Laboratory of Columbia University at the College of Physicians and Surgeons, New York. The viscosity varies with ether and chloroform narcosis and is not in constant relation with specific gravity. The mean viscosity of the blood of the dog is 5·5 times as great as that of distilled water. 5. On the Antitryptic Action of Serum Albumin, by S. G. Hedin, from the Lister Institute. 6. The Cilioscribe, an Instrument for Recording the Activity of Cilia, by W. E. Dixon, M.D. Lond., and O. Inchley, M.D. Cantab., with four figures in the text. 7. The Action of Adrenalin, by T. R. Elliott, M.A., George Henry Lewes student in physiology, with 12 figures in the text. This is a long and important article. Mr. Elliott observes that a positive reaction to adrenalin is a trustworthy proof of the existence and nature of sympathetic nerves in any organ. The stimulating effect takes place at the junction of muscle and nerve. The irritable substance at the myoneural junction depends for continuance of life on the nucleoplasm of the muscle cell, not on that of the nerve cell. 8. Observations on the Action of Trypsin, by S. G. Hedin, with two figures in the text. 9. The Normal Alveolar Carbonic Acid Pressure in Man, by Mabel Purefoy Fitzgerald and J. S. Haldane, F.R.S. It was found to have a mean value of 5·16 per cent. of one atmosphere in men, 4·78 in women, 4·89 in boys, and 4·63 in girls. 10. The Human Cardio-pneumatic Movements, by D. Fraser Harris, with five figures in the text. 11. The Action of Optical Isomers: (2) Hyoscines, by Arthur R. Cushing, M.D., and A. Roy Peebles, with two figures in the text. The Proceedings of the Physiological Society for May 20th and June 17th are included in these numbers, with the title page and the table of contents of the thirty-second volume of the journal.

Scottish Medical and Surgical Journal.—In the July number of this periodical are two papers of neurological interest—one by Dr. Edwin Bramwell upon a case of alexia in which at the necropsy there was found a lesion corresponding with the distribution of the posterior cerebral artery; and the second by Dr. J. V. Paterson on some cases of word blindness. An inaugural lecture by Dr. A. H. F. Barbour on the History of Obstetrical Anatomy calls merited attention to the work of some early writers in this field. Dr. G. R. Wilson deals with the occurrence of pain and with the peculiar symptom of sudden attacks of fear in connexion with cardiac disease, with a view to persuade general physicians to recognise the fact that mental symptoms are not things beyond ordinary medical ken but are closely allied to other nervous phenomena. Mr. J. Hogarth Pringle records a case of reversal of the patella—a twisting of the bone by external violence so that its posterior surface looks anteriorly—a rare form of injury.

Birmingham Medical Review.—In the number for June the second Ingleby lecture on Mentally Defective Children maintains the high level of interest reached by the first. We cannot, however, help regretting that a little more care was not exercised by the author over the wording of the lecture when it came into print, as the English here and there leaves a good deal to be desired: the matter is admirable. Mr. Charles A. Leedham-Green discusses the important question of marriage after the occurrence of gonorrhœa and shows that there is a difference of opinion as to what constitutes proof of a satisfactory cure. Dr. W. Murrell records two cases of ulcerative colitis and advocates the use of solutions of argyrol—a silver preparation—in the treatment of this condition.

Looking Back.

FROM

THE LANCET, *SATURDAY*, August 11, 1827.

The Hospital OUT-PATIENT system, and the *Public Infirmary* and *Dispensary* systems, are reducing those GENERAL PRACTITIONERS, who happen to come within their influence, to distress and beggary. Yet there is no Act of Parliament, no Surgical Charter to remove, or even check, this growing evil. The little influence our College does possess, is used to augment it, by holding up hospital surgeons as men of a superior grade, thereby bestowing honour on those individuals through whom the great majority of the profession are so much injured, both in reputation and in purse. It surely was never intended by the FOUNDERS of hospitals, that persons in affluent circumstances should become the objects of their generous bounty; that respectable TRADESMEN should attend as OUT-PATIENTS, and be supplied with medicines and advice GRATUITOUSLY; yet such is the practice to an almost incredible extent, thus depriving private practitioners of that emolument to which they are justly entitled. It appears, that in the statement published by some of the Governors of the London Hospital, who did not relish the late job, that the number of OUT-PATIENTS at GUY'S was underrated, and the following correction (evidently official) was forwarded to *The Times* immediately after the error appeared:—

> "Under the head of London Hospital, in *The Times* of Tuesday, the especting 3rd inst., an incorrect (doubtless of such Guy's Hospital having been mad at Guy's statement is now sent for inserti ysicians, Hospital the in and out-patients we house 3; assistants ditto, 1; surgeons, 4; apothecary, 1; total, 9; nearly 8000 pupils, 3; grand total, 12. Now, of out-patients alone, the last received relief in the last four months of 1826, and during (15,268) past six months of this year, 1827, upwards of 15,000 only have been already relieved. The out-patients, though generally only once, are often seen frequently, in the week. There is, indeed, require it one regular admission day for them; but all cases that It are continually attended to, whenever they present themselves. the Hos- may also be mentioned, that the regular number of beds in endowment pital exceeds 400. Of such an establishment, formed by the which of one man, its governors and officers, and even the country in Thomas Guy was born, may surely justly be proud."*

So that FIFTEEN THOUSAND TWO HUNDRED AND SIXTY-EIGHT out-patients have been already relieved at GUY'S, during the last past six months of the present year. Here is a pretty system. RELIEVED, be it remembered; how many there have been maimed and killed, Mr. HOSPITAL PUFF does not tell us. Now, when we reflect that medical practitioners are never backward in tendering either advice or medicine *gratuitously* to a truly distressed object, when we likewise reflect that the poor laws have secured medical attendance to the PAUPER, there is something in the above puff that excites our warmest indignation. THOMAS GUY, we take it, did not intend to be one of the destroyers of the medical profession, to found a shop for quacks, or to give medicines to such as do not require or deserve them.[1]

The *Times* of August 10th, 1905, has the following interesting excerpt from its issue of Saturday, August 10th, 1805:—"It is a lamentable fact that the Small Pox is extending its ravages, not only in the metropolis, but in many populous cities and towns of the kingdom, to a degree unexperienced for several years. It is believed, that at present about *fifty persons die weekly*, by this disease, in London and its environs. In one house there have been eleven deaths. The mortality at Norwich has also been considerable; in consequence of which, a meeting has been convened, at which the Mayor of that city presided; and it has been resolved that a General Inoculation for the *Cow Pox* shall immediately take place. Surely it is high time, that prompt and efficacious measures were taken, to stop the further ravages of that fatal disorder in the metropolis."

Curiously and appropriately, in the same number of the *Times* (August 10th, 1905) an announcement appears that a memorial tablet was on August 9th erected by the London County Council on No. 14, Hertford-street, Park-lane, where Edward Jenner resided in 1803.

* *Times*, July 5, 1827.

[1] Excerpt from leading article.

THE BRITISH MEDICAL ASSOCIATION.

MEETING AT LEICESTER.

ON July 26th the members of the Association were entertained in the evening at the museum buildings of Leicester by the Midland branch of the Association. The magnificent museum buildings, together with the art gallery adjoining, were thrown open for the occasion and the grounds were beautifully illuminated. Unfortunately heavy rain somewhat marred the enjoyment of those who wished to be in the gardens but the valuable collection of pictures and the very fine show of antiquities served as a solace for the disappointment. Naturally enough great attention was bestowed on the celebrated picture of "Orlando pursuing the Fata Morgana," presented to the town by the artist, Mr. G. F. Watts, R.A. The entertainment of the guests was further provided for by the clever artistes called "The Follies," and in a large upper room Mr. Harrison Hill, the well-known society entertainer, drew crowded audiences. Praise must be also given to the band of the Royal Artillery (Portsmouth).

The annual breakfast given by the National Temperance League to the members of the British Medical Association was held this year on July 27th in the Temperance Hall at Leicester, Dr. J. W. Leigh, the Dean of Hereford (the President of the league), being in the chair. The great feature of the meeting on this occasion was the presentation of an address of appreciation to the medical profession by the National Temperance League on behalf of the whole temperance movement in recognition of the important services which have been rendered to the cause of temperance by the medical profession through its progressive research and its declarations as to the nature and effects of alcohol. Speeches in support of this address were delivered by the Dean of Hereford, the President of the Association, Dr. C. K. Millard, Dr. Harry Campbell, and Dr. R. Jones. The proceedings terminated with a vote of thanks to the Dean of Hereford, which was proposed by Mr. W. McAdam Eccles and seconded by Mr. T. Laffan.

On July 27th Mr. R. C. Stewart, the President of the Leicester Medical Society, entertained the members of the Association and their friends at a garden party in the grounds of the County Asylum which is situated a little way out of Leicester on the London-road; and on the same day a garden party was given by Mr. Maurice Levy, M.P., and Mrs. Levy at Humberstone Hall, near Leicester. Special electric cars conveyed the guests to Humberstone and Mr. and Mrs. Levy received over 300 visitors, the ceremony of introduction taking place at the end of the famous avenue of cedars leading to the Hall. The performance by local amateurs of a clever comedy entitled *The Duchess of Bayswater & Co.* was quite worthy of the applause which it evoked and the Imperial Prize Band delighted a number of the visitors. Altogether this entertainment must be reckoned one of the successes of the meeting. In the evening the ladies committee, under the presidency of Mrs. G. Cooper Franklin, contributed to the gaiety of the meeting by providing a most enjoyable entertainment in the King's Hall at the Grand Hotel, Leicester. The hall was most tastefully decorated and Mrs. Franklin received many congratulations on the success of her efforts. An orchestra with glee singers and other vocalists discoursed music and the crowded apartments testified to the popularity of the fair hostesses.

On July 28th Mr. S. Faire, J.P., and Mrs. Faire opened their magnificent place at Glenfield Frith to the visitors and contributed to their enjoyment by holding a garden party for the occasion. The comfort of their guests was studied to the smallest detail: electric tramcars ran from the centre of the town to the Groby-road terminus where carriages were waiting to convey the guests to Glenfield Frith. Mr. and Mrs. Faire had secured the services of the band of the Royal Artillery and the playing of this band during the afternoon was much appreciated by the musical enthusiasts amongst the party. The splendid weather and the lovely grounds insured the success of the gathering, as every other detail had been carefully thought out. On the same day a party of visitors strictly limited to 60 visited Belvoir Castle, travelling in special saloon carriages to Stathern. Lunch was served in the train and on arriving at Stathern station private carriages were found waiting to convey the party through the beautiful woods of the district to Belvoir Castle which was reached shortly after 3 o'clock. Here the most complete arrangements had been made to insure that all the wonderful and interesting antiquities of the place should be seen. This magnificent pile of buildings stands high on a hill commanding lovely views over the vale of Belvoir and the celebrated gardens were in the perfection of their beauty and deserved the admiration of the visitors. Tea was served in the castle and the party shortly afterwards left for a pleasant drive to Redmile station whence the return journey was made to Leicester.

On the night of Friday, July 28th, Mr. and Mrs. Stephen Hilton, the Mayor and Mayoress of Leicester, gave an evening fête in the Abbey Park of the town. 40,000 fairy lamps of every shade of colour were placed on the lawns and in the beds of the park and in addition thousands of Chinese lanterns swung from the branches of the trees. The sight was extremely pretty and the waters of the lake reflecting the shimmering points of light rendered the scene a veritable fairyland. The guests numbered over 2000 and Mr. and Mrs. Hilton were unable for some time to move from the large marquee in which they received the visitors. The stream of guests, however, slackened sufficiently for the Mayor and Mayoress to be able later to move about the grounds and at half past ten a marvellous display of fireworks was witnessed, the last set-piece wishing "Good-night" and "Success to the Members of the British Medical Association."

The excursion to Buxton on July 29th proved a great success, the number of the party proceeding to this favourite watering place being about 120. Buxton was reached by special train a little after 11 A.M. and the first item on the programme for the day was found to be a visit to the baths and afterwards to the Devonshire Hospital. The arrangements were excellent, the medical men of the town, under Dr. C. W. Buckley, taking charge of small groups of visitors and personally explaining the equipment of the bathing establishment. The programme for the remainder of the day was of a most varied description and it is difficult to do justice to the organising capacity of the reception committee which seemed to have foreseen and to have provided for all the possible wants and pleasures of the numerous visitors. A lunch was served at the Palace Hotel to a great number of the party, Mr. H. A. Hubbersty, J.P., presiding, and being helped by Dr. Buckley in entertaining the guests. The toast of "The Guests" was proposed by Mr. W. Armstrong and responded to by Dr. T. D. Griffiths and by Dr. J. Brassey Brierley. The Bishop of Salisbury was also present and took part in the proceedings by saying grace. The remainder of the visitors lunched at St. Ann's Hotel where the hospitality was as open-handed as at the Palace Hotel. After lunch the visitors had a great many entertainments to choose from. Conveyances were in attendance to take those who wished to play golf to the splendid links on the heights by the town. Those who wished to go to Castleton were taken to the Midland Railway and arrangements were made for a visit to Chatsworth and Haddon or to Matlock. Some desired to see the Goyt Valley and were promptly provided with carriages. Others chose shorter drives and visited the "Cat and Fiddle," enjoying the splendid upland scenery so characteristic of Buxton. Some elected to remain in Buxton and for these special tickets were procured for the Buxton Gardens where a first-class band was playing. Wherever the visitors went they found that the reception committee had provided for the refreshment of the inner man and tea was procurable at the different refreshment kiosks, at the Empire Hotel, on the terraces, in the gardens, and in the luxurious lounge adjoining. The Union Club dispensed hospitality to the visitors and Poole's Cavern was inspected by many. Some of the party desirous of revisiting the Devonshire Hospital spent a part of the afternoon under the guidance of the members of the medical staff in going over the different cases. The return journey to Leicester commenced at 7 o'clock and all were unanimous in praising the reception committee for what it had done.

On July 28th Professor William Stirling gave the "popular lecture" at Leicester on the subject of "Fatigue and Repose," and lantern slides of well-known pictures emphasising special points of the subject were projected on the screen and were much appreciated by the people of Leicester. For the purposes of this meeting Professor Stirling had printed some attractive antique paper covers with striking extracts from Cervantes, Shakespeare, Keats, Hood, Spenser, and others relating to sleep and rest, containing reproductions of nine pictures and prints—viz., a portrait of Andreas Vesalius; prints showing the superficial muscles of man from Vesalius's "Fabrica Humani Corporis" (Basel), 1543; portrait of the anatomist Nicolaus Stenonius; and prints of the following paintings: "Victory, O Lord!" by Sir John E. Millais, Bart.; "St. Catherine," by Sodoma; "Worn Out," by T. Faed; "Hard Times," by Hubert von Herkomer; "The Stonebreaker," by H. Wallis; and "The Anatomy Lesson," by Rembrandt. The lecturer stated that mental fatigue caused bodily fatigue and *vice versâ*, and emphasised that severe muscular work and great mental activity were incompatible—at least, for most persons the double tax was too heavy. Teachers in schools knew that the effects of excessive mental work could not be immediately compensated by prolonged sleep, the remedy consisting of diminished work and increased recreation. In addition to sleep naturally obtained, true repose for many a weary brain was to change to some unexciting but useful occupation. Professor Stirling also, when commenting on the continuous strain of standing, said that it was easier to walk and to keep moving than to stand.

A neat and interesting souvenir of the British Medical Association's meeting at Leicester was issued by Messrs. Burroughs, Wellcome and Co., entitled "Leicester Medical Lore and Lecture Memoranda, B.M.A. Meeting, 1905." It consisted of a pocket book with a green leather cover bearing the arms of Leicester and containing 35 pages relating the history of Leicester illustrated by pictures, especially from the medical point of view, a note relating to the British National Antarctic Expedition, 32 ruled pages for lecture memoranda, and a synopsis, formulary, and abridged price list of the products of the firm. The points especially dealt with in the historical account are the Roman occupation of Leicester; the ancient abbey of St. Mary de Pratis, or St. Mary of the Meadows, and the death therein of Cardinal Wolsey; the plagues in Leicester in 1342, 1361, 1564, 1593, 1603, 1610, and 1623, to which a note is added that Leicester escaped the dread disease that decimated London and other large towns in 1665 and has not since been visited by the plague; the hospitals in Leicester, the first of which is said to have been founded for lepers in 1169; Leicester folk medicine, dealing particularly with a curiously spelt list of "prices of oyles and other lickwids" by John Frisby between 1723 and 1774; and notes on Robert Burton, author of "The Anatomy of Melancholy," who was a Leicestershire man.

THE SECTIONS.

MEDICINE.

FRIDAY, JULY 28TH.

A discussion was opened by Dr. J. **DRESCHFELD** (Manchester) with an address on

The Diagnosis and Treatment of Cardiac Degeneration apart from Valvular Disease,

based upon the following headings: 1. Acute myocarditis, especially in connexion with typhoid fever, diphtheria, pneumonia, and influenza. 2. Chronic myocarditis. 3. Myocardial affections in connexion with chronic infectious diseases (syphilis, malaria, and tuberculosis). 4. Cardiac insufficiency due to chronic intoxication: (*a*) exogenous toxins (alcohol, tobacco, and lead); and (*b*) endogenous toxins (Bright's disease, diabetes, gout, Graves's disease, cancer, and cachexia). 5. Myomalacia due to arterio-sclerosis. 6. Heart muscle failure in chronic lung affections. 7. Heart strain due to excessive muscular exercise. 8. Fatty heart. 9. Senile heart.

Dr. W. P. **HERRINGHAM** (London) said that in speaking of cardiac degeneration it was impossible to give anatomical grounds for the condition while the case for physiology was still weaker. They were driven to clinical observation and no experiments could check observation. The largest class of sufferers included elderly people, those exhibiting arterio-sclerosis, hypertrophied heart, and morbus renum. Those who developed definite hypertrophy lived longer than those who did not. Under stimulation the peripheral resistance was increased by contraction of the smaller arteries, while the larger elastic ones yielded to internal pressure. Endarteritis was due to impurities in the blood, such as those present in syphilis, diabetes, and nephritis. In young people these might always be traced to kidney disease, while in elderly people they resulted from excessive feeding, the habits of youth and middle life in the matter of excessive eating and drinking being continued at a time when the muscles were working at half speed and half time. After acute fevers, especially typhoid, there was degeneration of the cardiac muscle as in diphtheria. Rheumatism caused dilatation of the heart due to myocarditis or degeneration of muscle which might result in acute cardiac failure. Acute myocarditis occurred in rheumatic fever and in syphilis, while in the latter there might also be failure from gumma or the succeeding cicatrix. Dr. Herringham quoted three cases in big muscular men with primary syphilis where there had been no rheumatism or definite cardiac lesion, and of these one died, the heart exhibiting no valvular or other definite change beyond hypertrophy and dilatation, the paresis apparently resulting from interstitial myocarditis. Alcohol and tobacco impaired the vigour of the heart muscle and the œdema associated with alcoholic subjects was familiar enough. In young adults, like soldiers, growth and development threw extra work on the heart which perhaps in some individuals did not grow adequately to meet the extra strain. Acute dilatation of the organ was frequently met with after over-exertion, such as climbing or cycling. So many anatomical and physiological conditions produced the same ultimate effect that exact diagnosis was practically impossible. Roughly speaking, hearts yielded from intrinsic muscular weakness or owing to external stress; sometimes both causes were at work. This classification, however, afforded a fair indication for treatment.

Dr. A. **FOXWELL** (Birmingham) speaking of chronic forms of myocarditis said that it was impossible to diagnose that due to syphilis from local manifestations either clinically or post mortem. It, however, seldom occurred alone, the endothelium being likewise affected and in association with valvular lesions, dilatation of the aorta, or arteritis of the pulmonary vessels, the smaller branches being less affected. Where the heart was large with a feeble impulse and low arterial tension or with hard peripheral vessels a diagnosis of syphilitic myocarditis might be hazarded. Closely allied to these changes was the pulmonary atheroma in chronic lung disease, such as fibroid change, bronchiectasis, and emphysema, in which the vascular change was symmetrically and generally distributed and not restricted to the diseased side. There was right heart hypertrophy and often a great degree of pulmonary arterio-sclerosis was associated with a limited amount of lung disease. The sclerosis resulted from the raised blood pressure necessary to carry on the circulation at sufficient rate through the diminished circulation area, especially while the patient was leading an active life; this was associated with right heart hypertrophy, though this did not take place as readily as on the left side. In connexion with cases of heart strain Dr. Foxwell suggested that this was not solely the result of effort, there being in many cases evidence of previously existing disease shown by incomplete recovery and he cited one case in a middle-aged man who recovered partially after alarming symptoms. For six years the heart gave trouble on slight provocation and showed signs of dilatation and hypertrophy. With advancing life the organ came nearer its limits of repair and diminished activity of brain and muscle with reduced food were necessary to maintain life within its capacity. This patient was still living and in moderate health but with a loss of weight of one and a half stones to his advantage. In another case severe mental strain resulted in a syncopal attack lasting an hour. Seven years before the heart had been reported on as weak and two other members of the family had large weakly acting hearts. This was apparently a "heart family," the muscle being of weaker character and less resistance than normal. Another case was that of a patient, aged 60 years, whose heart failed in hurrying to catch a train, this occurring, no doubt, at the end of a long process of degeneration. He never recovered sufficiently to work again, being reduced to a lower rate of living consistent with the diminished heart power. The diagnosis of fatty heart was very difficult and was made too often. The organ was not necessarily enlarged and panting, sighing respiration with weak pulse were significant. The alcoholic heart exhibited imperfect muscle striation suggestive of the change in "cloudy swelling." The treatment of heart failure involved a most fascinating study, requiring the nice balancing of various functions and parts of the organism against each other, especially the vessels, kidneys, lungs, skin, and muscles. Over-stimulation of the heart in these circumstances shortened life, while if action fell below a certain degree life failed from pulmonary œdema. Lessening external work for the heart by diminishing life strain and relaxing vessels, &c., conserved its energy to overcome internal difficulty and so regulated the balance within the scope of its powers.

Dr. J. HAY (Liverpool) restricted his observations to the condition of the venous pulse in the neck. In health tracings showed a wave with the auricular contraction and another due to the impact of the carotid pulse; with myocardial degeneration, whether associated with valvular disease or not, the auricular contraction wave was absent and there resulted the ventricular form of pulse wave. Either the auricle was paralysed or it contracted with the ventricle as in experimental stimulation of "Gaskell's bridge," the rhythm being controlled by the auricular canal. As the heart tone was regained there resulted a fuller radial pulse preceded by the auricular wave in the jugular vein. When the inception of the heart impulse occurred at the auricular canal instead of the auricle the beat was inefficient.

Dr. S. WEST (London) spoke of cardiac failure in pyrexia and acute fevers, such as accompanied rheumatic hyperpyrexia and sunstroke or diphtheria and influenza. He referred to the observation of Stokes that the first sound was sometimes muffled in fevers and not necessarily in cases with the highest temperature. It was a serious warning of trouble and in one of his own cases of typhoid fever was followed by relapse and death. In rheumatic cases the young house physician was generally anxious to get the patient up as soon as the fever declined, the effect on the heart being often serious. Some cases of acute fever and severe illness as the cardiac form of influenza required care for a year before recovery was complete as regarded the heart and this was not surprising when the slow recovery from overstrain in an athlete was considered. In chlorosis with fatty change in the myocardium strain soon showed itself and dilatation involving considerable displacement of the apex came and went with exertion and rest and this was also the case in valvular disease. Failure of the heart in pericarditis was not surprising seeing that the pericardium was continuous with the interstitial cardiac tissue, so that both were necessarily involved together. When the heart failed the tissues to suffer first would be those the veins of which were nearest and these were those of the heart itself; so that a vicious circle was early established, described by Jenner as congestion of the heart. In treatment the susceptibility of the degenerated heart to digitalis was to be remembered. Small doses were sometimes useful but the cumulative action might be very speedily illustrated, the beats falling from 150 to 40. The drug should be given cautiously and suspended at once when such warning was given.

Sir JAMES GRANT (Canada) cited two cases of aortic stenosis in which life had been extraordinarily prolonged and he insisted upon the importance of careful attention to all the tissues and functions of the body in the treatment of cardiac disease.

Dr. W. EWART (London) pointed out that regular mechanical effort assisted the heart while mental strain embarrassed it. Most cases were treated effectually without powerful drugs, as Sir James Grant had indicated. The heart wanted time to feed and to rest and this small doses of digitalis might supply; otherwise careful regulation of diet, rest, and the normal bodily functions afforded the best means of cure.

The PRESIDENT of the section (Dr. F. M. POPE, Leicester) pointed out that heart failure occurred in the summer, seldom in the winter. Arrhythmia was due to failure of a thin auricle.

Dr. J. MACKENZIE DAVIDSON (London) gave an interestin demonstration of

The Use of the X Rays in Medical and Surgical Work,

with the aid of numerous lantern slides, with the object o showing the uses and limitations of the method. One poin upon which he specially insisted was the importance o always taking the [illegible] In 189 a method of preci [illegible] l and th stereoscopic method on Dec. 3rd, 1899. Small particles o metal or glass had been located in the eyeball or orbit t the one-fiftieth part of an inch. Calculi of various kind and in divers positions were demonstrated by actua skiagrams of the patients. Other cases were aneurysm o the aorta, diverticulum of the œsophagus, probing of th frontal sinus from the nose, subdiaphragmatic abscess, sho in the orbit, half the portal vein injected, showing independence of the circulation in the two halves of the liver and fracture of the head of the femur in reduction of congenital dislocation.

Dr. BERTRAND DAWSON (London) read a paper on

The Diagnosis of Gastric Ulcer,

in which the two well-defined types of ulcer were alone considered. Epigastric pain related to food. Localised tenderness, vomiting, and hæmatemesis were shown to be characteristic of other non-malignant affections of the stomach beside ulcer. Such were dyspepsia of anæmic young women (anæmic dyspepsia), gastritis caused by oral and pharyngea sepsis (septic gastritis), and hæmorrhagic gastralgia. A large number of the milder cases classed as gastric ulcer were due to anæmic dyspepsia. This was shown by a comparative study of clinical and pathological statistics, by the effects of treatment, and from the fact that out of a series of 24 cases under 25 years of age operated on for marked symptoms of gastric ulcer, in five a careful search within the stomach failed to disclose the ulcer. Similar cases were quoted in which no focal lesions were found at the necropsies. Dr. Dawson regarded these cases in anæmic young women as liable to acute invasion by ulcer. He further showed how septic conditions of the teeth, mouth, and naso-pharynx produced a gastritis with the same symptom complex as gastric ulcer, and how when the cause was removed the gastric symptoms quickly recovered. The diagnosis between gastric ulcer and these other conditions resembling it was considered. Acuteness of onset, complete intermission between acute attacks, non-subsidence of symptoms after a few days in bed, and recurrence of symptoms, especially *hæmatemesis while in bed,* were points in favour of ulcer. Pain in ulcer was accentuated by food, except in some cases where the situation was at the pylorus, in which food

---

[1] Brit. Med. Jour., Jan. 1st, 1898.

alleviated it. The length of time that pain occurred after food did not, however, throw light on the locality of the ulcer. This was shown by the examination of 102 cases operated on at the London Hospital. Deep localised tenderness was more suggestive of ulcer when it continued after the subsidence of other symptoms than during the attack. It was not caused by pressure on the ulcer. Tenderness of the skin over the upper abdomen occurred in anæmic and neurasthenic dyspepsias as well as ulcer, but when the diagnosis of ulcer was established the tenderness of the skin was a guide to its severity and progress though not to its locality. Increase in the free hydrochloric acid of the stomach was a characteristic of most cases of ulcer. In the diagnosis between chronic gastric ulcer and early carcinoma attention should be paid to the motor function of the stomach and to the presence or absence of free hydrochloric, lactic, and butyric acids and pepsin. A microscopical examination of the fasting contents was also of value. Free nuclei of leucocytes and other cells and sarcinæ were usual with the presence of hydrochloric acid and Oppler-Boas bacilli in large numbers with the presence of lactic acid. Clumps of pus cells with blood cells pointed to ulceration. By combined microscopical and chemical observations a correct early diagnosis was rendered possible.

SURGERY.

FRIDAY, JULY 28TH.

Mr. J. JACKSON CLARKE (London) read a paper entitled

A Note on Congenital Dislocation of the Hip-joint and its Modern Treatment.

He considered that congenital dislocation of the hip-joint was now a curable affection and this advance in surgery was due to Lorenz who evolved the manipulative and gymnastic method of treatment. When the patient was of suitable age the operation was without serious risk. The greater part of the after-treatment could be carried out at home under the care of the family medical practitioner. The patient invariably improved in general health and strength during treatment. The profession in this country had not yet appreciated the scientific basis and technical details of the treatment. Two years must elapse before the final results could be considered. From the experience of 17 cases which Mr. Jackson Clarke had treated by Lorenz's manipulative method in the last two and a half years he considered that the open operation was no longer justifiable and that cases of double dislocation were as well suited to the method as unilateral dislocations. The results were illustrated by photographs which showed complete restoration to the normal form and function of the previously shortened limbs and deformed spines. Experience in the method enabled the surgeon to avoid dangers.

Mr. JORDAN LLOYD (Birmingham) considered the Lorenz method a reasonable operation. Courage was necessary in its performance, because the force to be exerted was great. Lorenz had shown how far they could go with safety in these cases. He thought it a mistake to promise too much to the parents. The cases could be improved but even in the most successful cases the result was not perfect.

Mr. C. R. B. KEETLEY (London) thought that the prognosis depended chiefly on the age of the child. Before three years of age it was possible to promise a perfect result but even then the promise should not be absolute. He was inclined to think that many of these cases were not really congenital in origin but were traumatic. In certain cases it was possible by a stout silver wire passed through the neck and the anterior superior spine to keep the head in the acetabulum. The wire might be left in for four or five weeks.

Sir CHARLES B. BALL (Dublin) considered that the risks of the open operation were well worth running in order to obtain an exact knowledge of the conditions present.

Mr. JACKSON CLARKE, in reply, pointed out that Lorenz had renounced the open operation in favour of the manipulative method. Lorenz had been the first to point out the importance of the rôle of the muscles in maintaining the head of the femur in the acetabulum. Some of the defects after the operation were sometimes due to the existence of coxa vara. The after-treatment was of great importance. It might be said that in 90 per cent. of the cases under four years of age the prognosis was good.

Mr. KEETLEY read a paper on

Appendicostomy.

This operation, he said, consisted in bringing the appendix through the abdominal wall and opening it externally. The indications for the operations were muco-colitis, dysentery, obstinate chronic constipation, and syphilitic ulceration of the large intestine with hæmorrhage. The mode of performance of the operation might vary but it was important that the appendix should not be twisted. The presence of even many adhesions around the appendix was not a positive bar to the operation. He thought it important that the base of the appendix should be pulled close up to the parietal peritoneum. Unless the case was urgent the appendix should not be opened till the second or even the fourth day. The operation was painless and speedy and local anæsthesia of the abdominal wall was all that was needed. The first operation was performed by Robert F. Weir of New York. In all nine cases had been recorded and seven of these were successful and even the other two were none the worse for it; Mr. Keetley had performed the operation twice. The first patient was a girl, aged 15 years, who had had very severe constipation all her life. Her bowels rarely acted more frequently than once a week and on one occasion 24 days had elapsed without a motion. Now she had a daily motion by injecting some saline aperient through a catheter and she was much better in health and did not suffer from the severe headaches which she had before the operation. The second case was one of ileo-cæcal intussusception and Mr. Keetley employed the operation to anchor the cæcum.

Mr. PERCY FURNIVALL (London) had opened the cæcum in five cases for colitis, dysentery, and similar conditions. The colon was then washed out, beginning with a very mild solution of silver nitrate, say 1 in 400, about a pint being used. Three of the cases did well but in the other two no effect followed. He thought it an objection to appendicostomy that if the patient recovered the opening would not close.

Professor HOWARD A. KELLY (Baltimore) thought that in America at least there would be a great risk of the operation being overdone. It must be suitable for only a few cases. In his opinion many cases of colitis really affected only a part of the rectum and therefore might be treated by local applications.

Sir CHARLES BALL asked as to the amount of leakage and whether any dressing was required. He quite agreed with Mr. Keetley that it was desirable to anchor ileo-cæcal intussusceptions and he was in the habit of putting a stitch through the meso-appendix and fastening it to the posterior abdominal wall.

Mr. KEETLEY, in reply, said that there was no leakage at all in either of his cases and the opening itself was very small. He did not think that there was any need to close it and, indeed, it was convenient to have such an opening, as one never knew what might happen.

Mr. J. F. THOMSON WALKER (London) read a paper entitled

A Note on a Specimen of Bladder and Urethra removed Two Years after Prostatectomy.

The paper was illustrated by lantern slides. The patient from whom the specimen was taken had had suprapubic prostatectomy performed by the late Mr. Herbert W. Allingham at St. George's Hospital. 15 months before the patient died he had hæmaturia and death resulted from a malignant growth of the bladder. This growth, however, was quite separate from the prostatic cavity which still formed a well-marked space, lined by an irregular epithelium, and outside the epithelium was much new muscular tissue.

Mr. H. L. BARNARD (London) asked whether stricture ever followed prostatectomy. In one case he found when he examined the prostate that he had drawn out half an inch of the membranous urethra. By a misunderstanding of his instructions the bladder was not washed out per urethram for three weeks and when he examined the case he found the floor of the bladder closed and only a dimple marked the former urethral opening. He was able by forcibly pushing a catheter through to restore the patency of the canal. To avoid this danger he advised that the prostate should be removed in two pieces and that the bladder should always be washed out per urethram. The drainage tube should be removed from the bladder by the seventh day at latest. In one case he had operated on a small fibrous prostate and he had been only able to get it away in shreds, yet the patient did well. He thought very highly of the acid phosphate of sodium as an acidifier of the urine. It should be given as a beverage of the strength of a drachm to the pint. It was best not to operate until the urine was acid and then no phosphates would be deposited on the edges of the wound.

Mr. W. **SHEEN** (Cardiff) had removed a small fibrous prostate weighing only five and a half drachms. The patient recovered completely.

Mr. **JORDAN LLOYD** thought that strictures might occur after prostatectomy. In some cases a "diaphragm" might develop between the bladder and the prostatic cavity. In small fibrous prostates there might be a stricture between the bladder and the urethra.

Mr. **WALKER**, in reply, said that the specimen which he had obtained was the only one known in which two years had elapsed since the enucleation. He did not think it possible for the prostatic urethra to remain intact even if the prostate were removed in two pieces.

Mr. A. H. **TUBBY** (London) read a paper on

Spinal Osteomyelitis.

He referred to the rarity of the cases and the scanty literature. Three degrees of the affection were recognised: (1) a comparatively mild form, from which the patient recovered; in this form there were acute inflammation and thickening of the periosteum; (2) a more severe form, involving the periosteum and superficial layers of bone, which might or might not go on to suppuration; and (3) a violent form, in which suppuration occurred and where meningitis and myelitis were constant complications. The object of the paper was to call attention to the less acute varieties, and illustrative cases were given of the first and second degrees which had occurred in his practice. In both these cases, although there were rigidity and deformity of the spine, full recovery occurred within 12 months with complete restoration of function. The connexion of stomatitis with suppurative periostitis of the cervical spine was very marked and in both the cases described acute inflammation of the gums and alveolar margins had preceded the onset of the spinal symptoms. With regard to the violent form it was usually due to invasion of the spinal column by streptococci or staphylococci and the exciting causes were local septic disorders, such as boils, inflammation of the gums, septic nasal and naso-pharyngeal affections, mastoiditis, whitlows, or osteomyelitis elsewhere. It often followed pneumonia, scarlet fever, or measles. In six out of 41 cases there was a history of local injury. The disease was more common in children and adolescents but it was not confined to them. It occurred twice as frequently in males as in females. The lumbar region was most commonly attacked and then the cervical. The neural arches were more often affected than the bodies of the vertebræ. The local symptoms were tenderness, agonising pain on attempting to move, and there might be a localised œdema if the neural arches were affected. Nerve symptoms might be present and a case had been diagnosed as Landry's paralysis. The diagnosis of disease of the bodies was very obscure but if the neural arches were inflamed the diagnosis was easier. Suppuration occurred in 24 out of 62 cases. Important points in the diagnosis were the history of sudden onset, the early appearance of rigidity of the spine, the complication of acute nerve symptoms, the rapid development of intense general illness, and the complaint of agonising pain in the back. The prognosis in the periosteal cases was favourable but the more violent types were very fatal, the mortality varying between 50 and 75 per cent. In the milder varieties without suppuration rest in the recumbent position, followed by the use of a spinal support, was all that was necessary. In the suppurative cases pus must be found and let out at the earliest possible moment.

Mr. R. T. H. **BUCKNALL** (London) read a paper on

Two Cases of Operation involving the Thoracic Duct.

The first patient underwent an operation for tuberculous cervical glands of the left side for the third time. Within 24 hours of the operation he became very weak and a clear yellow fluid was observed to be flowing from the wound to the extent of from two to three pints a day. The patient steadily lost strength. The wound was explored and it was found that about two inches had been removed from the thoracic duct. The free end from which the chyle was flowing was tied. The patient soon improved and the wound healed. He died two and a half months later from miliary tuberculosis. The second patient was a woman whose breast had been removed for malignant disease two years previously. She had some enlarged glands in the posterior triangle. These were removed and it was found that the thoracic duct had been slowly occluded.

Mr. **BARNARD** referred to the researches of Mr. Cecil H. Leaf who had shown that there were many junctions between the venous and the lymphatic vessels. He (Mr. Barnard) had twice ligatured the thoracic duct without any harmful results.

Mr. **JAMES BERRY** (London) read a paper on

67 Cases of Cleft Palate treated by Operation, with special reference to After Results, and a Demonstration on Ten Cases.

He stated that the main object of the paper was to give an exact account of all the cases of cleft palate that he had treated both in hospital and in private practice in the hope that he might thereby induce other surgeons who employed different methods to do the same. All his cases had been treated on a uniform plan on the lines of the well-known operation practised by his old master, Sir Thomas Smith. He did not think that the advantages of the operations in very early infancy either by large flaps or by the forcible approximation of the maxillæ had at present been proved. He considered the third year of life to be the best period for the cleft palate operation in most cases and that the third month was the best period for the hare-lip operation. Of his patients 43 had been operated on over the age of four years and this was later than he liked. They were mostly patients in whom operation had been unsuccessfully performed by other surgeons or had been declined by the surgeon or by the parents. In no case under the age of 20 years had he ever declined to attempt an operation, however wide the cleft, and he exhibited photographs of some exceedingly wide clefts which he had completely closed. He laid great stress on the complete detachment by curved scissors of the soft palate from the posterior edge of the palate bones and also on placing the lateral incisions sufficiently far outwards and backwards. He pointed out the great importance of a moveable soft palate in the production of speech. He maintained that the view advanced by Mr. Arbuthnot Lane that the reason of the peculiar speech was that the outgoing air did not pass through the nose was totally opposed to the facts. Mr. Berry mentioned the chief consonants which were mispronounced by those with cleft palates and said that the changes were due to air escaping through the cleft and through the nose. With regard to the forcible approximation of the superior maxillæ he thought the operation unjustifiable. Of ten cases published and unpublished, which were all that, to his knowledge, had been performed in this country, four had died as the direct result of the operation. The cleft of the palate underwent a natural diminution, even without any operation, but especially if the hare-lip had been treated. The results of Mr. Berry's 67 cases were given in a paper distributed at the meeting. None of the patients had ever been seriously ill. In three cases only Mr. Berry did not succeed in closing the cleft but none of these had yet had a second operation. As to the speech, although he admitted that in no case could it be said absolutely to be perfect, yet in several cases it closely approximated to perfection, and in very many cases it was good. It was remarkable how much improvement occurred in patients operated on as late as 14 or even 18 years of age. Mr. Berry did not claim any originality in the method he employed, except in details. He thought it would be well if those who advocated extensive operations in the first year of life would give their results, especially as to the soft palate and the speech. A demonstration was given on ten of Mr. Berry's cases brought for the purpose; the patients' ages ranged from two to 16 years and the period since the operation from eight months to nine years.

Sir **CHARLES BALL** concurred in the importance of the detachment of the soft palate.

Mr. C. F. **CUTHBERT** (Gloucester) inquired as to the position of the patient preferred by Mr. Berry. He himself placed the patient so that the head hung over the end of the table.

Mr. W. M. **WILLIS** (Nottingham) mentioned that he had attempted Brophy's operation but complete necrosis of the bones resulted and the child died.

Mr. C. P. **CHILDE** (Southsea) employed Hagedorn's circular needles for the cleft-palate operation and not special needles.

Mr. **BERRY**, in reply, said that the patient was always in a sitting position with the shoulders raised and the head thrown back. The anæsthetist must be very skilful. He preferred rectangular needles and always used one silver stitch with a Smith's needle.

Mr. W. J. de C. Wheeler (Dublin) read a paper on

The Talma-Morrison Operation.

The patient was a man 47 years old. There was no history of alcohol. He was six feet high but weighed only eight stones. He had great ascites and on tapping two and a half gallons were drawn off. The liver was then found to be enlarged. 14 days later two gallons were removed. Then the abdomen was incised below the umbilicus but the fluid re-accumulated. Then the abdomen was opened above the umbilicus and the omentum was drawn out. The upper surface of the liver was scraped with a blunt Volkmann's spoon and then the diaphragmatic peritoneum was rubbed with a cloth and some peritoneum was shifted from the abdominal wall. The operation was performed nine months ago; the patient had been tapped once since and two pints were drawn off but since that he had been well and able to do his work. He had gained 2 stones 7 pounds in weight.

Mr. Sheen read a paper on

A Case of Ligature of the Innominate Artery.

The patient was a man, 46 years old, with a pulsating swelling above the right clavicle and the aneurysm involved the second and third parts of the subclavian artery. Mr. Sheen tied the innominate but the pulsation returned the following day. At a subsequent operation the subclavian artery was tied in the second part and the aneurysm consolidated. Nine months later the patient was still well.

Mr. J. D. Malcolm (London) read a paper on

Two Cases of Partial Sloughing of the Vermiform Appendix.

In these cases small gangrenous patches occurred in the appendix without any symptoms. Mr. Malcolm considered that they could not be due to inflammation and looked upon them as analogous to the "spontaneous sloughing" of the wall of the stomach.

Mr. W. Sampson Handley (London) gave a lantern demonstration on

Epigastric Invasion of the Abdomen in Surgery of the Breast.

He believed that the embolic transfer of cancer particles along the trunk lymphatics to the axillary glands and thence to the supra-clavicular glands and the blood was a mere side issue in the process of dissemination. The main agent in the spread of carcinoma was "permeation"—that is, the centrifugal growth of tendril-like lines of cancer cells along the fine vessels of the lymphatic plexuses. The process of visceral dissemination began as soon as permeation had traversed the fine lymphatic anastomoses of the body wall and had reached the lymphatic plexuses underlying the pleural or peritoneal endothelium. Cancer cells then escaped into the serous cavities and attacked the serous surface of the viscera. Immediately below the ensiform cartilage the subperitoneal fat was separated from the lymphatic plexus of the deep fascia—the plane of the parietal growing edge of a cancer of the breast—merely by a single layer of fibrous tissue, the linea alba. The epigastric region, therefore, proved the weak spot in the defences of the body cavity and cancer of the breast frequently reached the peritoneum by this route before it had succeeded in penetrating the thick thoracic wall. Hence in about 12 per cent. of all necropsies metastases were found in the abdomen, while there were none in the thorax. The capital defect of the present operation for cancer of the breast was that it ignored the danger of epigastric invasion. The risk must be met by excising the epigastric deep fascia down to a point two inches below the tip of the ensiform cartilage, a step involving no technical difficulty and not adding to the risk of the operation. The erroneous belief that cancer of the breast spreads along the skin had, especially in America, led to the removal of an unnecessarily large area of skin. It was usually sufficient to remove a circle of skin from four to five inches in diameter, centred on the primary growth. A linear incision, two inches long, running downwards over the ensiform cartilage from the circular incision afforded access to the epigastric region and another linear incision joining the outer part of the circular incision was required to give access to the axilla. The flaps should be undermined in all directions and a circular area of deep fascia from nine to ten inches in diameter removed, with the pectoralis major, except perhaps the clavicular portion. This operation had one immediate advantage—the skin edges could be approximated without any tension. The nutrition of the flaps remained excellent in spite of their extent and rapid healing with freedom from pain and pyrexial disturbance was thus insured.

STATE MEDICINE.

Friday, July 28th.

Bailie W. F. Anderson (Glasgow) opened a discussion on

Infant Milk Depôts.

He said that in view of the appalling death-rate of infants he had communicated with the British consuls of 60 of the leading cities of the world to discover how England and Scotland compared with other countries. He had been supplied with the total population and the general and the infantile death-rates. He found that in one or two cities where the general death-rate was high the infantile death-rate was distinctly lower than that of Great Britain. The only reason he could find for this was that milk depôts had been established. In Glasgow a central milk depôt was in full work and with very gratifying results. The principal details of the scheme were thoroughly pure milk, put into absolutely clean bottles and then sterilised. The cost was 2*d.* a day for the milk needed for the youngest infant, increasing to 2½*d.* and to 3*d.* with the increase of age. There were undoubted difficulties. Often milk was only obtained for infants when they were practically at death's door from intestinal disorders. Then when the child had improved with the pure milk a return to the old method of feeding would be made with disastrous effects. There were no means to get accurate statistics except in the case of infants who were taken to the central depôt. These could be weighed and watched. Lastly, there could be no doubt that there was some difficulty with dairymen and the annual cost was not at present met by the payments made for the milk.

Dr. T. D. Lister (London) considered that future health might be made or marred during the first year of life. The numerous deaths from starvation and from acute and chronic intestinal disease were to a great extent preventable. But many infants were damaged for life by improper milk. He considered that the provision of infant milk depôts gave the most satisfactory solution for exterminating bad or starvation foods. The occurrence of scurvy from sterilised milk was rare and in reality constituted nothing more than a bogey. Out of 21,000 infantile deaths some 50 per cent. were due to improper food but only seven were ascribed to scurvy. If a case of scurvy occurred in connexion with a milk depôt it showed that there had been a lack of proper supervision of the infants supplied. Each case ought to be under a medical certificate. It was impossible to wait for a pure milk-supply but the municipal milk depôt would be a strong factor in bringing about such a pure supply.

A contribution to the discussion by the Hon. Nathan Straus (New York) was read by Dr. C. Killick Millard. Mr. Straus showed that in that city one out of every three died before five years of age. Because of this appalling mortality he had started a private milk depôt. His plan was to provide pasteurised milk to the poor at a uniform charge of 2½*d.* a day. The indirect results of the effort had been quite as important as the direct. The milk-supply in the neighbourhood had greatly improved. He pointed out that there had been a very appreciable diminution in infant mortality and gave statistics from a hospital for waif children in which the death-rate was decreased from 42 before the introduction of the milk to 16. He was convinced that the effort should be rather municipal than private because of the great demand created.

Dr. Philip Boobbyer (Nottingham), the President of the section, believed that there was much in favour of municipal milk depôts and that the movement would be a permanent one. One principal discouragement was that it did not appear that they could be made to pay. Scurvy from sterilised milk, he was sure, was nothing more than a mere bogey. He instanced the effort made in his district by which the sewage farm was made to supply the required milk and provided an excellent object lesson to milk producers.

Dr. H. Cooper Pattin (Norwich) stated that the causes of infantile mortality were often pre-natal and that the dieting of parents was an important prophylaxis.

Dr. T. Whiteside Hime (Bradford) said that a milk depôt was merely another factor in relieving a mother of her responsibility to her offspring. The quality of the milk supplied, in his experience, was not good and was not the material for young infants. Ordinary cow's milk was nothing but poison for them; they needed a lac-albumin.

Dr. T. F. S. Caverhill (Edinburgh) contended that milk was the proper food for infants and that the public needed instruction in the necessity for pure, clean milk. There were only a few water-borne diseases and yet great attention was paid to the purity of water, while there were at least ten diseases propagated by milk and still the milk trade was merely prevented from being fraudulent. It was a sad fact that near Edinburgh in the rural districts there was the highest mortality among infants.

Dr. D. S. DAVIES (Bristol) urged that there should be trained health visitors in all districts supplied by the milk depôts.

Afterwards a joint discussion with the Section of Laryngology, Otology, and Rhinology on

The Infectivity and Notification of Diphtheria, with special reference to Latent Forms of the Disease,

was held.

INDUSTRIAL HYGIENE.

FRIDAY, JULY 28TH.

Mr. W. F. DEARDEN (certifying factory surgeon for North Manchester) opened the first discussion by reading a paper on

Accident and Poisoning Reports.

After some introductory remarks, in which he mentioned that the status of the certifying factory surgeon was not what it ought to be, he reviewed the various Factory Acts in their relation to the work of the certifying factory surgeons, and commented on the unsatisfactory nature of the time limit of disablement to qualify for notification. He then gave an outline of the duties of the certifying surgeons and stated that the surgeon had four factors on which to base his judgment of the actual causation of an accident—namely, the evidence of the employer or his agents; the evidence of the injured person; the understanding he himself had acquired of the machine, apparatus, and process; and his knowledge of the necessary particulars respecting the injury. The duty of devising methods of protecting dangerous machines devolved upon the inspector and the surgeon's report enabled him to decide when a visit from him would be necessary for this purpose. As these appointments were mostly held by medical men in general practice who were well known to both employer and employed there was seldom any difficulty in obtaining the information required. The systems of accident certification in France and Holland were then reviewed. In France every accident occurring to a workman whilst engaged in his occupation must be reported to the mayor of the municipality within 48 hours. The mayor notified the inspector of factories and also the magistrate of the ward who made an inquiry and transmitted the result to the president of the civil court of his division. This official had power to make an order in permanent disablement and fatal cases fixing the amount of compensation. In Holland the administration of the law concerning industrial accidents was under the control of a department of State insurance. Any medical practitioner could, on application, be appointed a medical officer of this department. Compensation was settled by the directorate of the department acting under the advice of a chief medical referee. Compensation was granted to the extent of 70 per cent. of the average weekly earnings. Mr. Dearden considered that these systems formed a good object-lesson for our legislators and suggested that the factory surgeon's report would prove a useful aid in determining the length and degree of disablement. He was of opinion that the present system of investigating accidents suffered from the want of a general supervision by a principal surgeon who should have a thorough practical understanding of the work. The reporting upon cases of industrial poisoning by the certifying surgeon was quite a modern requirement though it had already borne excellent fruit. A large number of occupations came under the regulations of the Factory Act of 1895 in this respect. Persons who had to handle foreign hides and skins, wool-sorters, and workers in foreign hair were liable to be attacked by anthrax. The poisonous effects of lead were most prominent in connexion with the manufacture of white lead, paints, and colours, electrical accumulators, metal smelting, printing, tinning and enamelling, file-cutting, and glass polishing. Galvanising works and the manufacture of emerald green were mainly responsible for arsenical poisoning; lucifer-match making for phosphorus poisoning; and the trades of hatters, furriers, makers of thermometers and barometers, electro-gilders, and manufacturing chemists for mercurial poisoning. The number of cases of lead poisoning in the year 1899, according to the chief medical inspector of factories, was 1258. This number had been reduced to 597 in 1904 and a corresponding reduction occurred in the case of other industrial poisonings. The remarkable reduction in cases of lead poisoning had mainly taken place in the pottery industries and the manufacture of white lead owing to the careful supervision exercised over those trades by the special rules brought into force.

Dr. THOMAS WATTS (Hyde) expressed himself as very pleased that the Government had dropped the Accident (Mines and Factories) Bill. He was of opinion that the passing of that measure in its original form, which would have involved doing away with direct notification to the certifying surgeon, would have been a retrograde step in factory legislation and would practically mean that very few reportable accidents would be notified at all.

Mr. C. F. BRYAN (Leicester) commented on the great benefit accruing from the report of the certifying surgeon under the Workmen's Compensation Act. He considered the time limit objectionable because serious symptoms, such as septicæmia, &c., might supervene later in persons who had been able to work for five hours on the three days following an accident. He would like to see cases of accidents not due to machinery but, e.g., to faulty stairs reported to the surgeon in the first instance.

Mr. SEYMOUR KNYVETT (H.M. Inspector of Factories, Birmingham) agreed with previous speakers as to the importance of the certifying surgeons' reports and considered that owing to their intimate local relations with employers and workpeople they might have a greater opportunity for unfettered inquiry than in the case of the inspectors. He also gave a tribute to the excellence of the work done by lady inspectors. He could not agree with the suggestion that the surgeon's investigations should form an item of expert evidence in cases taken to the law courts for compensation, as the surgeon's reports at present possessed a confidential character, absolutely essential to their utility, which would be lost in their preparation for public evidence. He earnestly advocated an extension of the time limit and hoped that the section would do all in its power to extend the reporting of illnesses, especially of diseases acquired by workers in brass.

Dr. H. W. LANGLEY BROWNE (West Bromwich), the President of the section, considered that records should be kept of the duration of disablement of an injured person. These would be valuable for future reference. In France, Germany, and Austria all accidents were graded on a regular scale, No. 1 representing the slightest accident causing disablement from work and No. 100 representing fatal accidents or those causing permanent disablement. Some such system as this might avoid conflicting medical evidence in courts of law. He considered that the post of certifying surgeon should be combined with that of medical referee under the Workmen's Compensation Act and often with that of medical officer of health. The officer should be well paid and put in the same position as other inspectors both as to salary and pension.

Mr. DEARDEN then briefly replied.

Dr. D. J. A. CHOWRY-MUTHU (Wells) introduced the next subject for discussion,

Poverty in relation to Disease and Degeneration.

He expressed the opinion that all the social evils of the present day had been the outcome of trying to enjoy the sweets of civilisation without attempting to take up the responsibility which that civilisation brought with it. When men like Mr. Charles Booth declared that 30 per cent. of the entire population of London were unable to obtain a livelihood; when Mr. J. S. Rowntree stated that from 25 to 30 per cent. of the town populations of the United Kingdom were living in poverty; when they were confronted with the fact that about 400,000 people in London alone were living a one-room life, where decency was not possible and morality was a farce, then England was face to face with a terrible problem requiring all her strength and wisdom to solve. It was one of the ironies of the present-day civilisation that while this country was constantly extending its borders in circumference, in the very centre of the empire its sons and daughters found no room to live in and went about the streets in want of the barest sustenance that was not denied to the so-called savage or the Hottentot. Poverty robbed the physical efficiency, dulled the intellect, filled the mind with dread and despair; constant underfeeding led to the slow starvation of all the organs of the body, which could not perform their work efficiently. The curse of poverty followed a man from childhood to the end of his life. In infancy a large majority of the children could not get the natural food of their mothers because so many of these mothers were themselves underfed or obliged to be at work all day and therefore unable to suckle their children. The consequence was that the growing generation was to a very large extent fed on artificial food which aggravated the precariousness of their lives and increased infant mortality to an alarming extent. Dr. E. W. Hope of Liverpool had stated that the deaths in that city among children under three months old either wholly or partially fed on artificial foods were 15 times as great as they were among an equal number of infants fed on breast milk. Three-fourths of the 150.000 infants who died annually in this country during the first year of life had been fed artificially. The slaughter of the innocents was not the only result of poverty and overcrowding. The condition of the children who survived was worse than that of those who died in infancy. A very large proportion of children attending schools were underfed. How could the child who went to school constantly hungry give heed to lessons or do justice to education? The lack of food impoverished the body, interfered with the calcification of the teeth and the formation of sound bone, and caused stunted body and rickety constitution. The speaker from his experience in the East end of London could corroborate the views of Dr. William Hall of Leeds as to the superior development of Jewish children, which was due to their being better fed and cared for than the children of the Christian poor. He considered that consumption was not so much a microbe or filth disease as a disease of poverty. With regard to the remedies for the state of affairs described, he considered that the system of workhouse and Poor-law relief had not been a success, because it was worked on the principle that no man should receive help till he was destitute and broken down. They allowed their people to become paupers, vagrants, lunatics, drunkards, and criminals, and then built workhouses, prisons, asylums, and almshouses for them, which was like letting a patient reach the last stage of consumption and then erecting a sanatorium to save his life. Dr. Chowry-Muthu strongly recommended the adoption in this country of some such system as the Elberfeld system as worked in Germany. This was an organised attempt on the part of well-to-do city men to give their services freely to look after the poor and to relieve their several necessities without pauperising them. Every effort was made to find work for the unemployed. All help to the needy, the sick, the aged, and the infirm was controlled by one central agency without fuss or friction. So elastic was its work that even the provision of coals, blankets, garments, soup kitchens, &c., was administered by this system, and so economically was it managed that it had saved hundreds of pounds to the ratepayers ever since it had been instituted. The system of compulsory insurance of working men against accident, sickness, convalescence, and old age as adopted in Germany was also well worth the study of England. In conclusion, he suggested the adoption of milk depôts, women inspectors to instruct the mothers in feeding and hygiene, day nurseries where children could be looked after while the mother was at work, open-air schools in the country, and free meals for the children of the poor and destitute. They wanted a systematic organisation all over the country undertaken by the nation on behalf of the children. The money spent on the rising generation was a good investment and would yield a hundredfold in years to come.

Dr. C. E. **REINHARDT** (London) considered the question more a political than a medical one and traced the poverty of England to four conditions: (1) the state of land tenure, in which the man who did least work reaped most benefit; (2) over-population, the most fertile being those who lived in the worst surroundings; (3) disease, especially consumption; and (4) alcohol. As remedies he advocated the garden city scheme, in which the land belonged to the people; free education and support of children; reduction of alcoholic consumption; and hygienic education.

Dr. J. **BROWN** (Bacup) considered alcohol the chief cause of poverty and disease. He thought milk depôts were useful but that it was more important to nourish properly the mothers so that they could provide their own milk.

Dr. J. **DARLEY WYNNE** (Clonmel) remarked that in Ireland the death-rate from consumption, instead of decreasing to a marked extent as it had done in England and Scotland during the last 50 years, had actually increased. Though the people in Ireland were very poor yet there was not so much abject poverty as in many large English towns and he thought they must not lose sight of the fact that dirt and bad sanitation were equally important factors with poverty in the causation of disease.

Mr. **BRYAN** referred to the fact that Leicester was about to start a milk depôt. Although a member of the sanitary committee he was not much in favour of the scheme. He thought milk ought to be given to the people free and urged the advisability of more medical men giving free lectures to the people on hygiene.

The **PRESIDENT** of the section considered that one advantage of sending children to school was that they were kept there in better surroundings than at home for a good part of the day. He was in favour of milk depôts. He thought they were going the wrong way about the treatment of consumption and should spend money on the improvement of the dwellings of the poor before they erected sanatoriums for them.

Mr. **KENNETH W. GOADBY** (London) read a paper entitled

A Preliminary Note on the Blood in Lead Poisoning.

He said it was notorious that workers in lead factories, and especially in those departments in which the workers were exposed to lead dust, suffered frequently from anæmia. The facies became very pale, often to a much greater degree than the actual blood count might indicate. Associated with the anæmia was a progressive loss of orbital and buccinator fat which, with other well-known appearances, made up the saturnine cachexia. Some little time ago Dr. T. M. Legge called his attention to a paper by Dr. Hamel in which were described the results of an examination of the condition of the red blood corpuscles in lead anæmia. In the paper referred to Dr. Hamel confirmed the findings of somewhat minute basophile granules in the red corpuscles of lead workers as had been noted by Lazarus, Grawitz, and by Plehn in malaria. These basophile granules were frequently found in various species of anæmias and had been the origin of a considerable amount of discussion as to their exact nature. Schumann had described their presence in bothriocephalous anæmia. From the staining reactions, in that they did not show a selective action with methylene green, Bloch considered that they were not nucleinic acid and that as they took a blue colour with Nocht's stain which coloured chromatin red they were not of nuclear nature. In staining with Leishman's stain the granules were a faint bluish green and were easily seen, the colour being entirely different from that of the nuclei of normoblasts. Grawitz concluded that the granules in question were a species of granular degeneration of the red cells and that they made their appearance when a good deal of blood destruction was in progress and he called especial attention to their appearance in plumbism as did Behrend, White, and Pepper. Hamel in the paper referred to above considered that the presence of these basophile granules was to be regarded as diagnostic of lead anæmia and gave the results of a number of individuals in which he found these bodies and considered that they were the first sign of lead intoxication. With regard to the general blood condition Hayem said that there was no increase of the hæmoglobin index. Malassez and Zimm both agreed that there was very little if any increase in the number of leucocytes. Oliver said that the hæmoglobin often fell below 50 per cent. and Osler was inclined to regard the anæmia as rarely more than a 50 per cent. reduction in the red corpuscles. All observers agreed that there was no leucocytosis. At the suggestion of Dr. Legge Mr. Goadby commenced to investigate the condition of the blood in lead poisoning some little time ago but owing to the pressure of other research he had been unable to devote as much time to the subject as it deserved. He had examined a number of films from cases of anæmia in three lead works, two of the factories being devoted to white lead manufacture, and the other including desilverising, smelting, reducing, and the manufacture of litharge. He could confirm the finding of basophile granules in a large percentage of the cases which showed a definite anæmia and in a few in which the anæmia was not at all marked, while those persons who were examined on their starting work for the first time in lead processes showed no Plehn's granules. The films were stained with Leishman's stain and with hæmotoxylin and eosin. Of 30 cases of distinct anæmia the granules were found in all but were apparently somewhat more numerous in the more severe cases. In the case of men who had been engaged in lead processes

A, lymphocytes; B, transitional; C, large mononuclear; D, polymorphonuclear; E, eosinophile; F, basophile; G, microcytes- H, megalocytes; I, poikilocytes; J, nucleated cells; and K, basophile granules in erythrocytes (Plehn's granules). Corpuscles, Thoma Leitz method. Hæmoglobin, Haldane's method. Films stained, Leishman's method..

for a considerable time the number of basophile granules was not so marked. The red blood cells in most of the cases he had examined showed a good deal of irregularity both in size and shape as well as in the reaction to the stain used. Irregular staining was common as was vacuolation. The erythrocytes of the blood in lead poisoning appeared to be damaged more easily in manipulation than those in other kinds of blood he had been working with and this might perhaps account for the somewhat irregular shapes which were so common. At the same time there were frequently present well-defined microcytes. Nucleated red corpuscles of any variety were, as far as he had seen, extremely rare, only a small number having been seen. The blood platelets appeared to be normal. He did not feel at present at all satisfied that the presence of the basophile granules was of such sufficient importance as to regard them as diagnostic of lead anæmia. They undoubtedly occurred in other conditions widely differing, while in two Italians he found these granules before they had worked at all in a lead process. They had suffered from "fever" in Italy. Their significance was probably confined to the marking of the establishment of some destruction of the blood and their appearance corresponded to the commencement of anæmia and did not antedate the affection. In the ten cases furnishing the blood counts given in the table a considerable reduction in the number of red cells was seen. In three instances this was very marked and was much below that given by Osler or Oliver. The men were all very pale but were doing their work without any complaint of feeling ill. Two of them showed no blue line. The hæmoglobin, except in two cases, corresponded to the corpuscular count. Little or no difference was observed in the staining properties of the leucocytes. The absolute number did not appear to be increased in any marked degree. In the differential counts there did not appear to be much change from the normal. If anything the lymphocytes were a little increased and the polymorphonuclear cells decreased.

There was no discussion and the proceedings terminated with a vote of thanks to the President of the section.

LARYNGOLOGY, OTOLOGY, AND RHINOLOGY.

WEDNESDAY, JULY 26TH.

This section met under the Presidency of Dr. F. W. BENNETT (Leicester) who delivered a brief address welcoming those present. He referred to the progress of laryngology and otology in Leicester and spoke of the importance of the subjects from the educational standpoint.

Dr. W. MILLIGAN (Manchester) and Mr. E. B. WAGGETT (London) opened a discussion on

The Lines of Treatment in preventing Acute Middle-ear Suppuration from becoming Chronic.

Dr. Milligan in his opening paper said that treatment should aim at cutting short extension of an inflammatory process and, if possible, before exudation had occurred. He advocated an early and free incision of the membrana tympani as of the most importance. One unnecessary paracentesis was far better than the risk of extension of the disease. Spontaneous perforation of the drum came too late and the resulting drainage was inefficient. He spoke of the possibility of spreading septic infection by the injudicious use of Politzer's air douche. Nasal and post nasal disease induced chronicity and should be treated. Dr. Milligan treated it surgically after the temperature had fallen and remained normal for five days; in the meantime he used antiseptic douches and sprays. To insure free drainage of the ear in acute cases he was in favour of incision of the mastoid. In the exanthematous cases if free incision of the drum failed in seven days to arrest the disease then he opened and cleared out the mastoid cells; in the non-exanthematous cases if after three weeks free incision of the drum had been inefficient then he performed antrectomy. In conclusion, he deplored the lack of teaching otology which he held to be in some measure responsible in the past for acute middle-ear suppuration becoming chronic.

Mr. WAGGETT'S line of argument was that the natural termination of an acute otitis was resolution and where chronic suppuration supervened that was due to certain conditions of an accidental nature. The chronic suppuration was in a sense a fresh disease and might be quite independent of the infective agent causing the initial acute otitis. In treating cases of acute otitis three main considerations must be kept in mind. 1. The assistance of the inflammation regarded as a wholesome reaction against an abnormal irritant. 2. The direct prevention of those accidents which underlie chronic otorrhœa. 3. The avoidance of any interference which might possibly engender or precipitate one of those accidents. Mr. Waggett applied these principles of treatment to serous, muco-purulent, and purulent cases respectively. 1. Where the exudate in the tympanum was merely serous and the reaction a mild one the case might as a rule be brought speedily to an end by medical treatment, rest and warmth in bed being the most essential. Paracentesis was only called for if pain were severe and it was to be regarded as a palliative and not as a hastener of the cure. 2. With muco-purulent catarrh, seen typically in the adenoid case, the best treatment was the immediate removal of the adenoids or other source of infection in the nose or post-nasal space. That measure not merely cut short the acute otitis but prevented chronicity, or, more strictly speaking, the frequent recurrence of the otorrhœa. Hot instillations of glycerine and carbolic acid, six grains to the ounce, would give relief of pain pending the operation, which should be done within 24 hours of the diagnosis. Where there was true pus in the tympanum neither medical treatment nor mere removal of the remote causes would suffice to prevent chronic otorrhœa following. It was the rarest thing to find an acute case becoming chronic where more careful treatment was adopted; on the other hand, out-patient rooms were filled with cases of chronic otorrhœa which had commenced in an acute attack. It amounted to this, that exclusive of tuberculous cases there was a vast number of chronic cases which would never have existed had they been treated thoughtfully during the acute onset. Those cases were chronic either because reinfection from without was constantly occurring or because the organ could not get quit of a source of infection within itself. To the former class belonged those cases which speedily yielded to mere toilet of the meatus or to the removal of purulent foci in the upper air passages. In the second class the trouble was essentially mechanical in origin, such as the difficulty of aseptic fluid draining from the recesses of the attic and mastoid, the impossibility of an inspissated sediment doing so, the impregnable position occupied by micro-organisms which had entered the Haversian canals. In the treatment of acute suppuration it was necessary, in the first place, to avoid injecting pus into the mastoid by using Politzer's bag. An illustrative case was given in which septic material was actually driven through a deficiency in the mastoid into the tissues of the neck. In the second place, free paracentesis must be performed without an hour's delay, if at the moment of inspection the pus might be upon the point of penetrating into the mastoid or the ulceration of the muco-periosteum be just reaching the bone and laying bare the Haversian canals. Even after paracentesis Politzer's inflation was useless as a method of cleansing and Young and Milligan's experiments had shown how it might carry a spray of pus to the mastoid antrum. All pus, Mr. Waggett continued, could not be completely removed from the ulcerated tympanum. It must therefore be kept as much diluted as possible with continuous or very frequent irrigation of the meatus. In the vast majority of cases that treatment, coupled with warmth in bed, suitable diet, the exhibition of salicylate of quinine and purgatives, and the instillation of glycerine and carbolic drops, would prove quite successful. Politzerisation must not be employed upon the healed ear until all redness had departed for a fortnight. Where pain, tenderness, and fever persisted in spite of such treatment the mastoid was involved. With medical treatment, cold applications or leeches, many of the cases got perfectly well. But even in the absence of all the classical signs of mastoiditis, including the dropping of the postero-superior wall of the bony meatus, a mastoid operation must be performed if a copious discharge persists. Such a discharge would be coming from a large ulcerated area of the muco-periosteum of the mastoid antrum and would insure a chronic otorrhœa if not dealt with by operation.

Mr. T. G. OUSTON (Newcastle-upon-Tyne) read a paper on

The Lines of Treatment in preventing Acute Middle-ear Suppuration from becoming Chronic.

The discussion was then thrown open.

Dr. A. A. GRAY (Glasgow) was in favour of delaying paracentesis unless it was certain that pus was present. He would postpone performing an operation, as suggested by Dr. Milligan, upon the mastoid.

Mr. T. MARK HOVELL (London) did not support politzerisation in acute cases. A bulging membrane he considered ought to be incised freely. An operation for the removal of adenoids he would postpone until the illness was over. The suggestions made by Dr. Milligan for improving the drainage by a mastoid operation were heroic measures. Leeches were better than hot fomentations when the pain was over the mastoid process. Medical treatment was not sufficient.

GYNÆCOLOGY AND OBSTETRICS.

FRIDAY, JULY 28TH.

The proceedings of this section were opened by Dr. HERBERT R. SPENCER (London), the President of the section, calling upon Dr. R. BOXALL (London) to begin the discussion

On the Treatment of Albuminuria and Eclampsia

by reading his paper. Dr. Boxall said that it was necessary to point out the intimate association between the presence of albumin in the urine of pregnant women and the occurrence of eclampsia. The cause of the eclampsia was in part obscure and there were many theories—maternal and fœtal, chemical, nervous and mechanical causes—which had all been given in turn from time to time. If renal disease occurred during pregnancy it was liable to be acute and severe. If renal disease existed previously to pregnancy it was always likely to be much aggravated. First pregnancies were very liable to be attended by renal disorder and perhaps the increased intra-abdominal pressure was a factor in causing it. Cases in which the uterus was much enlarged seemed to support this idea as renal disorders were prevalent in these cases. The albumin in the urine was usually paraglobulin. He reviewed the pathological conditions and the parenchymatous changes in the kidneys, liver, and other organs. The death returns showed that renal disease and eclampsia occurring in association with pregnancy and childbirth were important factors in maintaining the death-rate from accidents in childbirth. He showed by a table and chart the relative deaths from puerperal convulsions, that the rate in England was maintained at a constant level, that latterly the rate in Ireland and Scotland had risen to above that of England and Wales, and that the rate of London was always lowest and remained so and at a constant level. The treatment of eclampsia was considered from two points of view—prophylactic and remedial. The treatment of albuminuria during pregnancy, which was the expression of the pre-eclamptic condition, constituted the prophylaxis of eclampsia. It resolved itself into the prescription of a milk diet and the maintenance of free purgation, free urination, and free perspiration. The remedial measures were: (1) increasing the action of the eliminating organs—bowels and skin—by reinstating the action of the kidneys, assisted in some instances by blood-letting and saline injections; (2) by sedatives—chloroform, chloral, and morphine; and (3) if these means failed, by diminishing the intra-abdominal and intra-uterine tension, rupturing the membranes and emptying the uterus. The operative measures most suitable under varying conditions were discussed; the importance of effecting delivery, when labour had once begun, expeditiously but with as little disturbance of the patient as was possible was strongly insisted on.

Mr. E. HASTINGS TWEEDY (Master of the Rotunda Hospital, Dublin) complimented Dr. Boxall on his scholarly paper. He thought that the eclamptic fit was due to a poison generated in the mother or the fœtus and was probably deposited in the solid tissues. Œdema, so called, of the lungs was a common complication of eclampsia which had not been mentioned and was probably the result of medicine placed in the mouth of an unconscious patient. There might be œdema of the lung in certain cases, however, but more often than not it was caused by the medicine placed in the mouth of the unconscious patient. He did not believe in rapid delivery in unconscious cases. Morphine was given at regular intervals as a rule in most cases. The stomach was washed out and castor oil was passed down into the stomach by the tube, followed by saline injections. A similar tube was passed into the rectum and the bowel was repeatedly washed out. Subcutaneous injection of saline solution was often used and it appeared to be better than the intravenous injection. The first and second stages of labour were not interfered with, nor was labour induced but was left to come on by itself naturally, which it always did.

Professor J. W. BYERS (Belfast) thought that scientifically very little was known about the pathology of eclampsia. There might be several causes or processes at work. Primiparæ were the most frequently attacked and this fact should be carefully considered. At the Geneva Congress in 1896 he put the case strongly and pointed out that in certain localities eclampsia was more prevalent and also that in certain seasons of the year it was more prevalent. He thought that the fœtus was one factor in the causation of this disease. When the fœtus died early in the labour the cases appeared more mild. Twin cases were more liable to eclampsia than others of a single birth. He thought the morphine treatment was one which did a great deal of good; it unfortunately often killed the fœtus, however, but that might, from what had been said, be an indirect advantage in disguise. He thought that the prognosis was difficult and uncertain. The metabolism of the liver appeared to be the cause rather than disturbance of the functions of the kidney as was popularly supposed, the kidney being the victim of the shortcomings of the defective hepatic action. The morphine treatment was found to be better than the chloroform and chloral treatment, to judge from the Rotunda practice in Dublin. He thought that delivery might be profitably expedited in some cases.

Dr. MARY SCHARLIEB (London) said that in India she found that cases often showed lesions in the liver; often in these cases there was no albuminuria. They left cases as a rule to a natural onset of labour and did not interfere; and, for the most part, this treatment did not have anything but satisfactory results.

Dr. JOHN CAMPBELL (Belfast) thought that pregnancy had a tendency to bring out any weakness in the kidneys. Some cases showed a congenital history in which they or their relatives were liable to renal disturbances apart from pregnancy. He used morphine in his practice and started labour by rupture of the membranes and then left the labour subsequently to nature.

Dr. T. WILSON (Birmingham) said that about eclampsia very little was really known. He thought it might be due to one of many poisons. He did not use the chloroform treatment as freely as formerly advocated and only used it very reservedly. He did not find that morphine did much good. The subcutaneous and intrarectal injection of saline solution did most good. He found in his experience that the hurrying on of labour often did good service. A method that he thought might be of use was vaginal Cæsarean section, as it obviated the unsatisfactory and injuriously stimulating action of mechanical dilators, apart from their other objections.

Dr. A. N. HOLMES (Dublin) said that some of the worst cases he had seen were those which occurred after labour; in some of these cases there was marked jaundice. Morphine was not as a rule pushed sufficiently far by those who had abandoned it as not of much benefit. If those who had abandoned the use of morphine had only used it more freely, but with caution, he was sure their conclusons would have been different.

Dr. J. INGLIS PARSONS (London) thought that because the kidney had to do extra work was the reason why it became affected. He thought that if the fœtus was the cause of the eclampsia and albuminuria it ought to be got rid of. He adopted this course and therefore expedited labour and found it to be the best. He thought that saline injections were of service as he had found them useful in his own practice.

Dr. EWEN JOHN MACLEAN (Cardiff) said that the toxæmic theories and the mechanical theories had given rise to scientific pathological conflict. He had used Bossi's dilator but did not feel encouraged to use it again. The importance of early recognition of albuminuria in pregnancy was very great and when found the condition should be rigorously treated. In many cases there was no albumin in the urine, even where symptoms leading to suspicion of renal disease were present. He found thyroid extract very valuable in increasing the renal efficiency and strongly recommended its trial by others.

Dr. F. W. FORBES ROSS (London) said that Mr. Hastings Tweedy had stated, when referring to the possibility of the condition being due to a poison as one of the factors in causation, that he believed the poison to be in combination with the solid tissue, and Professor Byers believed the poison, on the other hand, was circulating in the blood. He (the speaker) thought that the clinical history and pathological conditions were such that both the former speakers were correct. At first the symptoms were those of a poison in the blood: headache, vomiting, dyspnœa, and albumin in the urine, with retarded metabolism, as instanced by the deficiency of waste products in the urine and the small amount of urine. Subsequently parenchymatous changes in the liver, kidneys, &c., and, finally, affection of the nervous centres producing convulsions pointed strongly to close combination with the solid tissues. The toxin of tetanus was known to be in organic combination with the cerebral cells and produced convulsions. Again treatment tended to support the former speakers. Saline injections by diluting the poison did good; just as water added to spirit retarded its action, so in the case of eclampsia that proportion of the poison in the blood was diminished in action. Mr. Hastings Tweedy had mentioned the benefit of blood-letting and had called attention to the fact that if subsequent intravenous injection of saline solution were overdone the symptoms would gravely relapse. Here blood-letting, by producing a flow from the tissues into the blood, would carry away some of the poison, which was evidently in loose combination with the tissues, from the cerebral cells and lead to improvement. Subsequent saline injection, if the poison was present in the blood above a certain proportion, would, by producing hydræmic plethora, tend to cause a flow of fluid from the blood into the tissues, which latter, entering into loose combination with the dissolved poison, removed it from the fluid and thus again gave rise to the nervous symptoms afresh. Professor Byers had said that he thought that the fœtus was one of the main factors in the causation of the disease leading up to eclampsia. The speaker was in strong agreement with this and quoted a case tending to support this idea.

Dr. C. E. PURSLOW (Birmingham) said that he had tried the active and the passive treatment of labour in eclampsia. He preferred the active treatment of the eclampsia and the passive treatment of the labour was most satisfactory. He used the saline treatment and found it valuable. He quoted two cases of illegitimate pregnancies in which the pregnancy was the first in each case and both the cases died and he was strongly of the opinion that shame or mental distress was a powerful factor in such cases which were frequent in illegitimate first pregnancies.

Dr. A. SHARP (Nottingham) said that eclampsia was a matter of great interest to the general practitioner. He thought that worry and trouble were two of the causes of the condition, or at least predisposed to it. The morphine treatment was the reverse of what had been hitherto advocated for kidney disease and for this reason its recommendation was a striking fact.

Mr. J. W. DRAPER (Huddersfield) said that certain cases in his practice had to be helped regularly by being delivered under an anæsthetic and he found that on the whole they multiplied.

Dr. HENRY CORBY (Cork) said that with regard to theory the profession was very much in the dark as to the causation of eclampsia. He said that if albuminuria was present in the pregnancy there was more danger of eclampsia in labour. He thought that the quantity and quality of urine as regards waste products were more important than the amount of albumin. He did not like the action of pilocarpine though he had used it. He had tried morphine and did not like it whether pushed or not. He approved of saline injections as they undoubtedly diluted the poison. He thought that the fœtus might be a cause, but not the only cause, of the condition.

Dr. J. FORD ANDERSON (London) said that his practice was that in cases of eclampsia he tried to avoid causing irritation and to remove sources of irritation. He found that chloroform was especially dangerous in eclampsia. He considered nitrite of amyl useful. All sources of mental excitement and worry should be, as far as possible, eliminated from the patient's surroundings both during gestation and labour. He was of opinion that there were many causes of eclampsia and that, although the condition might be due to a poison or poisons, still there were possibly other causes.

The PRESIDENT of the section thought that what was brought out clearly by the discussion was that there was not much known as to the pathology of eclampsia in general. What also was brought out was the gentleness of treatment adopted by those who had had most experience. Morphine was in his opinion useful for the convulsions, but, as Dr. Corby said, it should be used most cautiously as it might cause disaster. He did not approve of vaginal Cæsarean section or Bossi's dilators and condemned dilators generally. He did not find as great benefit from saline injections, bleeding, &c., as some appeared to have found. He thought that pilocarpine in this condition was not a good drug and should not be used.

Dr. BOXALL, in reply, thought that certain cases of eclampsia should be rapidly delivered and in these cases, where matters were urgent, it did not appear that waiting increased the chances of recovery. He thought a stomach tube should be used. He used morphine and found it satisfactory. He did not like mechanical dilators and was glad to find that the opinion of the President of the section and of the majority of the members of the section was in harmony with his own.

Dr. MACLEAN then read a paper entitled

A Case of Elephantiasis of the Vulva.

The case was illustrated by microscopic and ordinary photographs. The history showed the condition to have been present at birth and there was a possible specific taint in the father who lived for some years amongst the natives of Australia. The patient was single and 19 years of age and stated that whilst within her recollection the vulva had always been enlarged, at and after puberty the enlargement became progressively cumbersome, until latterly the dragging pain which was experienced on assuming the erect attitude had become very distressing and produced an almost complete incapacity for house work. The growth was found to be based in the labia minora and clitoral regions and was removed by amputation with very satisfactory after results. The microscopic nature of the growth was described and was followed by a *résumé* of the English and continental literature as to incidence, etiology, pathological anatomy, and treatment.

Dr. J. INGLIS PARSONS then read a

Further Report on his Operation for Prolapsus Uteri, with Notes of 93 Cases.

He had found it extremely useful for private patients who wished to get rid of wearing pessaries. These people did not object to an operation that was practically bloodless and left no scar and was to all intents free from risk. His operation of injections of quinine into the broad ligament had two advantages over hysteropexy: firstly, the uterus could expand and pregnancy was not interfered with; and secondly, the uterus could be held up when the abdominal wall was too flabby for a ventrofixation. Six of his cases had full-term children without any difficulty subsequently to operation. There was no pain after the operation and no rise of temperature occurred as a rule. He had gradually increased the amount of the solution injected into each broad ligament to one drachm of a solution the strength of which was 100 grains to the ounce, but found it advisable not to go beyond that amount. If its repetition was necessary it should certainly not be done before a fortnight had elapsed. For minor cases of prolapse rest in bed for ten days after the operation was enough if the patient wore a pessary for two months and kept herself recumbent until organisation had taken place. In dealing with chronic cases of procidentia of from 10 to 20 years' duration a proportionately longer time was required in bed, and two injections would in some cases be necessary, with an interval of a fortnight between each injection. The results were very favourable. Of the 93 cases 90 per cent. had procidentia, about 80 per cent. were completely cured of their prolapse, and only one case completely failed. In every case of minor prolapse, where the patients had chronic backache and were obliged to wear a pessary, the operation had succeeded.

Dr. FORBES-ROSS asked Dr. Parsons whether the improvement and cure were lasting and whether there was any tendency to recurrence. He said that it was very satisfactory indeed to find that Dr. Parsons was able to extend his experience of his operation and felt himself justified in repeatedly bringing the apparent marked benefits and advantages to the notice of the profession and congratulated Dr. Parsons on his highly successful percentage of cures.

The PRESIDENT of the section commented favourably on the high percentage of success.

Dr. PARSONS replied and said that cases after eight years showed no tendency to relapse of the pre-existing condition.

Professor BYERS in eulogistic terms moved a cordial vote of thanks to Dr. Herbert Spencer for his able and tactful conduct of the business of the section.—This was seconded by Dr. TAYLOR YOUNG (Sydney, New South Wales) in apposite and happy terms and he asked to be allowed to couple the names of the secretaries of the section, Mr. M. W. Williams and Miss Louisa Garrett Anderson, with the vote, which was carried by acclamation.—The PRESIDENT of the section thanked the members and felicitated Miss Garrett Anderson for the success of her efforts in organising the gynæcological section of the pathological museum. He also thanked Professor Wertheim and Professor Howard Kelly for their help in making the section a success.

OPHTHALMOLOGY.

FRIDAY, JULY 28TH.

Mr. E. TREACHER COLLINS (London) opened a discussion on

Capsular Complications after Cataract Extraction

by reading a comprehensive paper illustrated by lantern slides of microscopic sections. He divided the cases into two groups—namely, (1) those resulting from the adhesion of the capsule to the extraction scar; and (2) those resulting from opacity occurring in connexion with capsular remnants. On the first group he showed by sections of eyes which had been lost that fixity of the capsule in the corneal wound might arise from two causes—namely, (*a*) an entanglement within the lips of the wound; and (*b*) agglutination of the capsule to the back of the wound by inflammatory exudate. He detailed three cases in which the capsule became entangled within the wound and resulted in such serious after-effects that the eyes were lost. In each case there ensued severe serous irido-cyclitis and in two of them sympathetic inflammation was excited in the other eye with such serious symptoms as hæmorrhage into the anterior chamber, keratitis punctata, and hypopyon, with later increase of tension. Paracentesis was performed for the relief of the symptoms and in one case an attempt was made to release the adherent capsule from the wound. Microscopic examination of the scar of the eyes showed the following appearances: a thickening of the sclero-corneal tissue in the vicinity of the wound, due to the spacing out of the layers of fibrous tissue and infiltration of round cells; an elevation of the conjunctiva overlying it, due to a considerable accumulation of round cells beneath the epithelium; a prolongation, in finger-like processes, of the surface epithelium into the scar for some little distance; and a large accumulation of cells between the lips of the wound surrounding the entangled lens capsule. Nearest to the capsule many of these cells were of an epithelioid type. Within the line of the wound a corrugated piece of the anterior lens capsule was fixed at from half to two-thirds of the depth of the wound and the lips of the wound gaped apart, although in one case five months had elapsed since the removal of the cataract. He concluded from the features of the sections (1) that the entangled lens capsule acted as a foreign body and produced about it just that arrangement of cells found around a foreign body, such as an eyelash, implanted within the healthy cornea either accidentally or experimentally; (2) that the presence of the capsule in the wound delayed healing; (3) that the delayed healing increased the liability to infection by micro-organisms from the conjunctiva and therefrom ensued the irido-cyclitis; and (4) that a tendency to irido-cyclitis was predisposed to in these eyes by the constant drag kept up on the ciliary body through the entangled capsule. Either or both ends of a divided capsule might become agglutinated to the posterior surface of the wound or the inflammatory exudate on the posterior surface of the wound might extend between the two lips of the divided anterior capsule and unite the posterior capsule to it. This agglutination did not delay healing but it advanced the position of the lens capsule from that which it occupied normally and consequently advanced the position of the iris. This might be so marked that the root of the iris might be dragged into apposition with the posterior surface of the cornea so as to obstruct filtration and produce glaucoma. The existence of a previous iridectomy did not completely remove this risk. This agglutination of the capsule to the wound was not so serious a matter as the incarceration of the capsule within the wound. In some few cases in eyes with adherent capsule no increase of tension might occur until a subsequent needling operation was performed; this might result from a new and stronger attachment of the capsule which brought forward the root of the iris still further. In other cases the irritation of the ciliary body by the disturbance of the tense capsular remnant just sufficed to block filtration by a new exudate. Even if no seriously untoward effects resulted such eyes not uncommonly remained irritable for some time after interference. Mr. Collins next considered how these risks of capsular complication might be best avoided and what could be done to remedy the condition when found to exist. He believed that the operation of extraction without iridectomy was less liable to be followed by complications of this order (the iris interposed between the cornea and the capsule), yet the risk was not thereby wholly avoided. He had recorded a case where on removal of a lens in its capsule without iridectomy the anterior hyaloid membrane was incarcerated and ultimately caused glaucoma. He next considered the possibility of preventing the complication by taking special precautions in opening the capsule before the liberation of the lens. Capsulotomy by forceps seemed to afford the best protective as compared with capsulotomy by needling. It made sure of the removal of the loose central capsular remnant but did not eliminate risks of peripheral portions becoming entangled.

attacks of mould and the beetle exhibited by rice from different countries, and the association of the mould with articles of food other than rice—such as maize, sago, dried fish, &c.

After a short discussion, in which the PRESIDENT of the section, Dr. T. SHENNAN (Edinburgh), Dr. G. T. CLARKE, and Major G. H. FINK, I.M.S., took part, Dr. HAMILTON WRIGHT briefly responded.

Dr. W. PAGE MAY (London) gave a lantern demonstration of a remarkable series of sections of the brain and spinal cord of

A Case of Microgyria or Cerebral Hemiatrophy.

The right side of the brain was less than two-thirds of the size of the left and its convolutions, though not simpler in form, were less than half as rich in grey and white matter. On the affected side the large motor and pyramidal cells were absent or markedly degenerated, whilst the pyramidal layer and the inner line of Baillarger were notably diminished in size. There were similar degenerative and atrophic changes in the parietal and frontal regions and to a lesser extent in the occipital. The basal ganglia on the affected side were much wasted and also the pyramidal tract and fillet. The opposite (right) lobe of the cerebellum was wasted and the cells of Purkinje were absent or degenerated. Marked atrophy in the nucleus dentatus and in the superior cerebellar peduncle was also a striking feature of the condition, and whilst the tangential fibres in the cerebrum and cerebellum were slightly affected the large associational tracts were normal. In the spinal cord marked degeneration in the anterior horn cells was associated with degeneration in the affected pyramidal tract and in the antero-lateral column.

Dr. R. CATTLEY (Leeds) and Dr. A. S. F. GRUNBAUM (Leeds) then communicated their observations

On the Mitoses in the Cells of the Graafian Follicle.

They stated that some of the mitoses found in the Graafian follicle of the rabbit's ovary bore a strong semblance to heterotype division; so much so that one of them at first thought some of the divisions were of that type. Further investigation had not confirmed this opinion. The ovaries examined included those of the human female, of the chimpanzee, and of the rhesus monkey, as well as of other mammals. So far as they were aware no previous records existed concerning the mitoses in the Graafian follicles of the three first named. The best preservation was obtained with "weak" Hermann's fluid—viz., the ordinary formula with half the quantity of osmic acid—and iron hæmatoxylin was the stain most frequently used. Many other methods of preservation and staining were tried. The appearances in the rabbit were peculiar and, as could be seen from the lantern slides, more difficult to interpret than in other mammals, although in these also shortness and thickness of the chromosomes occasionally made it difficult to say that a particular mitosis was not heterotype. But although these particular mitoses, all in metaphase, bore some resemblance to such forms, yet the absence of any heterotype prophase in all the numerous sections examined made it extremely probable that there were *only somatic mitoses* present. Moreover, there appeared to be no reduction to one-half the ordinary number of chromosomes. The absence of heterotype divisions in other animals made it unlikely that the forms seen in the rabbits were really of that nature. Even in the rabbit's ovary there were numerous mitoses obviously of the somatic type and it would be contrary to all experience for the majority to be heterotype; and since their existence would have supported certain views as to the embryological origin of the cells of the Graafian follicle it seemed to Dr. Cattley and Dr. Grünbaum of some importance to establish the negative proposition that heterotype divisions did not occur there.

Dr. F. G. BUSHNELL (Brighton) and Dr. F. HINDS (Worthing) then demonstrated a series of wet preparations illustrating Some Aspects of Carcinoma Ventriculi: its Variations in Malignancy, and Dr. BUSHNELL further demonstrated a specimen of Red Degeneration—so-called Necrobiosis—of a Fibroma of the Uterus which had been removed and lent by Mr. T. H. Ionides, surgeon to the Sussex County Hospital.

FRIDAY, JULY 28TH.

Dr. SHENNAN, who occupied the President's chair, opened the proceedings by calling upon Major FINK who read a paper entitled

Cancer and Pre-cancerous Changes: their Origin and Treatment,

in which he contended that cancer was due to a parasite, most probably a fungoid growth or mycetozoon, basing his arguments on analogy with "kohlhernie," a disease of the cabbage plant which was investigated a few years ago by Woronin and Eidam and stated to be due to one of the myxomycetes termed by its discoverers plasmodiophora brassicæ.

In reply to a question by Dr. MOTT, Major FINK said that he had no specimens illustrating the subject of his paper to submit to the meeting.

Sir JAMES GRANT (Canada) spoke at some length on the value of the results now being obtained by workers in the field of cancer research, particularly those associated with the Imperial Cancer Research Fund and expressed the hope that the time was at hand when the results obtained by research workers would justify the opening of an active campaign directed against the dread disease. Passing to the economic value of abstract science to the State, Sir James Grant enlarged upon the freedom of the Japanese troops from such diseases as dysentery and typhoid fever, due, in the opinion of the speaker, to the fact that a highly trained staff of bacteriologists preceded the army and advised as to the localities to be chosen for camps, &c.

In the absence from England of the author, one of the secretaries read a paper by Lieutenant-Colonel C. BIRT, R.A.M.C., entitled

The Caffeine Enrichment Method.

The pronouncements of Roth in 1903 regarding the selective action of caffeine upon bacilli of the colon and typhoid groups raised the hope that a medium had been found which would encourage the growth of the bacillus typhosus at the expense of the bacillus coli, for Roth stated that the former thrived upon agar which contained 0·6 per cent. caffeine (trimethylxanthin), but that the latter was entirely suppressed. A year later Roth admitted that the caffeinated agar did not fulfil all requirements and he advocated preliminary incubation—i.e., enrichment—of the suspected material in broth faintly alkaline to phenolphthalein and containing from 0·8 to 1 per cent. caffeine and claimed to have obtained constant results with diverse races of colon and typhoid bacilli. Other workers—Hoffmann and Ficker, Reitsch, Courmont and Lacomme, and others—attempting to repeat Roth's observations, recorded very conflicting results; the last-named observers, however, recorded a very striking peculiarity of the bacillus typhosus, as they found that cultivations of this organism obtained from a patient's urine thrived in caffeine broth whilst those isolated from the blood died, and Horrocks noted similar behaviour on the part of the micrococcus Melitensis from urine and the spleen when inoculated into this medium. Lieutenant-Colonel Birt therefore experimented with 31 varieties of Eberth's bacillus—all typical in their morphological and cultural characters and in their serum reactions. After five days' incubation at 37° C. the tubes containing 26 out of the 31 strains were sterile and on repeating the experiment a like result was noted at the end of three days; five races grew freely in the 0·5 per cent. caffeine peptone water. Fæces from five enteric fever patients were inoculated into the caffeine broth, incubated at 37° C. for six hours, then plated on Drigalski and Conradi's agar, but no typhoid bacilli could be isolated. Negative results were also obtained in the examination of suspected water-supplies; control experiments where water was experimentally infected with the bacillus typhosus also failed. Lieutenant-Colonel Birt also studied the effect of caffeine on the growth of 18 strains of bacillus dysenteriæ, all identical with Shiga's bacillus and found that none would grow in this medium; nor could the bacillus be recovered from the fæces of dysentery patients by this method, although the colon bacillus could usually grow through. Streptococci (both from the intestine and from pus), staphylococci, bacillus proteus (from the human intestine), bacillus pyocyaneus, and bacillus paratyphosus, type B, all thrived in the medium. Lieutenant Colonel Birt concluded by stating that 0·5 per cent. caffeine in 1 per cent. peptone water did not always restrain the development of the bacillus coli, whilst 26 out of 31 strains of the bacillus typhosus and all (18) strains of the bacillus dysenteriæ were completely inhibited; therefore negative results could not be relied upon to exclude these organisms from dejecta or water. Caffeinated media were of service in isolating streptococci and staphylococci.

Dr. J. W. H. EYRE (London) said that the experiments which he had already carried out with caffeinated media and others that he now had in progress fully confirmed Lieutenant-Colonel Birt's results. He considered that the paper was a valuable one as it sounded an urgently needed note of warning to those workers who even now reposed confidence in caffeinated media.

Dr. BERTRAM ABRAHAMS (London) showed an extremely interesting series of lantern slides illustrating the

Morbid Anatomy and Histology of Various Forms of Acute and Chronic Diseases of Joints.

Skiagrams, photomicrograms, and photograms were exhibited from cases of rheumatism, acute and chronic arthritis deformans, gonorrhœal arthritis, infective arthritis, Charcot's joint, gout, and Still's disease. It was pointed out that in all instances in which an acute or subacute infective origin could be postulated the only change to be noted in the bones was a marked thinning of the epiphysial ends. There was never any trace of overgrowth or the formation of osteophytes. It was suggested that the difference between the acute and chronic varieties of arthritis deformans was dependent upon the length of time during which the patient was exposed to the influence of an intoxication and stress was laid upon the importance of the indications for treatment which might be derived from a careful pathological and skiagraphical study of individual cases.

Dr. MOTT, Dr. A. W. GILCHRIST (Nice), and Dr. SHENNAN took part in a short discussion on the subject of this demonstration.

Dr. EYRE and Dr. J. F. FLASHMAN (Sydney, New South Wales) communicated a paper on

Diphtheroid Organisms in the Throats of the Insane.

They briefly recapitulated the work of Dr. Ford Robertson whose results suggested the probability that general paralysis f the insane was caused by the invasion of the body, already eakened by syphilis, by some member of the diphtheria roup of bacilli—possibly the Klebs-Löffler bacillus itself—nd further that it was this organism or its toxin that gave he paralytic aspect to the disease; and they explained hat their investigation into the occurrence of diphtheroid rganisms in the throats of general paralytics and patients ith other forms of insanity at Claybury and Colney Hatch sylums was undertaken with a view to determine the tability of his premisses. By carefully analysing recent iterature dealing with the incidence of the bacillus diphtheriæ in the throats of the presumably healthy and normal individual on the one hand and of diphtheria "contacts" on the other, average figures were obtained which served as a basis for comparison. They then proceeded to examine in detail the material from the throats of 60 cases of general paralysis of the insane and of 78 cases representing other forms of insanity; and material derived post mortem from the throat, pharynx, bronchi, cerebro-spinal fluid, heart blood, bile, and scrapings from various portions of the intestinal mucosa of ten cases of general paralysis and 26 cases representing other forms of insanity. Whenever a bacillus resembling the bacillus diphtheriæ was noted in any of these situations the organism was isolated and thoroughly studied, its identity established, and its virulence tested. Incidentally the value of Neisser's stain in the differentiation of Klebs-Löffler bacillus was discussed and they expressed their opinion that Neisser's so-called differential stain afforded no information beyond that given more easily and more conclusively by a simple carbolic methylene-blue stain. They summed up their results by stating the percentage incidence of all "diphtheroid" organisms in the throats of the insane as 17·3 per cent, a figure not in excess of that noted (18·5 per cent.) in the same population outside the walls of an asylum. The percentage incidence of genuine bacillus diphtheriæ at 5·07 per cent. in the throats of the insane (a large proportion of the diphtheroid organisms noted were common saprophytic members of the diphtheria group of bacilli) compared well with 6·9 per cent. in the healthy sane. Dealing more particularly with general paralytics they were unable to satisfy themselves that the bacillus diphtheriæ was more common in their throats (5 per cent.) than in the throats of cases of other forms of insanity (5·1 per cent.), whilst the majority of the strains isolated were of low virulence and slight toxicity and so compared in these respects with the types found in the throats of the healthy sane. The number of cases (10) of general paralysis studied post mortem was too small to permit of trustworthy deductions but it was significant that the bacillus diphtheriæ was not met with in any. As the result of their work they were unable to trace any causal connexion between the bacillus diphtheriæ and general paralysis of the insane.

Dr. MOTT and Dr. SHENNAN took part in the discussion that followed.

One of the secretaries then read a paper by Dr. CECIL PRICE JONES (London) entitled

The Influence of Certain Micro-organisms on the Cellular Constituents of the Red Bone Marrow,

in which he described his researches in this connexion. The procedure adopted comprised—(1) the examination of bone marrow obtained from a number of presumably healthy rabbits and guinea-pigs; (2) the examination of bone marrow obtained from a number of these animals that had died from the effects resulting from the inoculation of cultures of different micro organisms, the rabbits being inoculated with the diplococcus pneumoniæ and the guinea-pigs with the micrococcus Melitensis; (3) the estimation of the watery content of the bone marrow obtained from these healthy and infected animals; and (4) the comparison of the above results with those obtained from the examination of bone marrow obtained from children who had died from various causes, including pneumococcic septicæmia, broncho-pneumonia, epidemic diarrhœa, &c. Dr. Jones referred to a note previously published[1] in which the technique and the classification which he employed were detailed but he advocated for the present purpose a more general classification of the cell elements of the marrow into *non-granular* or lymphoid cells, *granular* or leucocytic cells, and *nucleated red cells*, these last being expressed in percentages of the total number of the white cells counted in each case. A series of examinations of bone marrow from 11 healthy rabbits gave an average percentage differential count of 51·3 per cent. lymphoid cells, 48·4 per cent. granular cells, and 11·7 per cent. of nucleated red cells. A similar series from five healthy guinea-pigs gave an average of 43·3 per cent. lymphoid cells, 56·2 per cent. granular cells, and 8·04 per cent. of nucleated red cells. An example of healthy human marrow obtained from a man who was killed in a carriage accident gave a percentage cellular composition of 50·4 per cent. lymphoid cells, 49·5 per cent. granular cells, and 8·2 per cent. of nucleated red cells. A series of examinations of marrow from 13 rabbits that were inoculated intraperitoneally with the pneumococcus, and with three exceptions died within 24 hours of infection, showed a marked lympho-erythroblastic type of marrow, giving an average percentage cellular composition of 61·4 per cent. lymphoid cells, 38·1 per cent. granular cells, and 35·0 per cent. of nucleated red cells; whereas a series of five rabbits inoculated subcutaneously with the pneumococcus, and surviving infection at least three days, showed a leucoblastic type of marrow, giving an average count of 34·3 per cent. lymphoid cells, 65·4 per cent. of granular cells, and 15·0 per cent. of nucleated red cells. A series of examinations of marrow from five guinea pigs inoculated subdurally with the micrococcus Melitensis showed a lympho erythroblastic type of marrow and gave an average percentage cellular composition of 61·1 per cent. lymphoid cells, 38·4 per cent. granular cells, and 18·3 per cent. of nucleated red cells. A series of examinations of marrow from eight children who died from pneumococcic infection showed a pronounced leucoblastic type of marrow, with average percentage counts of 32·17 per cent. lymphoid cells, 67·75 per cent. granular cells, and 6·1 per cent. of nucleated red cells, the type being especially strongly marked in two cases in which empyema was present. Another series from five children who had died from dysenteric diarrhœa presented a marrow that differed only slightly from the healthy type, giving average percentages of 45·4 per cent. lymphoid cells, 54·5 per cent. granular cells, and 10 per cent. of nucleated red cells. Dr. Jones concluded, first, that infection by different micro-organisms resulted in the production of different types of bone marrow dependent not only on the virulence but also on the specificity of the organism; and secondly, that apparently a lymphoblastic marrow was usually accompanied by an increased production of erythroblasts, but that, on the other hand, a leucoblastic marrow was not associated with increased erythroblastic production.

---

[1] Brit Med. Jour.

Dr. P. J. CAMMIDGE (London) read a communication on

Observations on the Fæces in Biliary Obstruction and Pancreatic Disease,

first describing the methods he adopted for the examination of the fæces. After noting the naked-eye and microscopical characters of the specimen and the reaction to litmus the nitrogen was determined by Kjeldahl's method, the fat was estimated by a modification of the Schmidt-Stokes method for estimating milk fat, which was described in detail, and finally a rough colour estimation of the amount of stercobilin was made. Dr. Cammidge then summarised the results obtained in the examination of the stools from 53 cases of biliary obstruction and pancreatic disease, grouping his cases under five headings—viz., (1) stone in the first or second part of the common duct, eight cases; (2) stone in the third or fourth part of the common duct, nine cases; (3) chronic pancreatitis, 21 cases; (4) cancer of the pancreas, 13 cases; and (5) pancreatic diabetes, two cases. In colour the stools varied from white to a practically normal tint; but in all except the cases of cancer of the pancreas stercobilin was present and yielded a marked reaction; the reaction in all but those in which there was obstruction high up in the common duct was acid; muscle fibres were detected microscopically in all but cases of pancreatic diabetes; the percentage of total fat in the fæces showed wide variations, even in the same groups of cases, but was usually in excess of normal. Comparison of the percentages of neutral fat and fatty acids in the various groups of cases showed that when obstruction high up in the common duct seriously interfered with the entry of bile into the intestine the fatty acids showed an excess over the neutral fats; in all other lesions the neutral fats were in excess.

Dr. A. F. DIMMOCK (Harrogate) and Mr. F. W. BRANSON (Leeds) then demonstrated

A Rapid and Simple Process for the Estimation of Uric Acid.

The method consisted in the precipitation of the uric acid from a slightly alkaline solution as urate of ammonium and subsequently measuring the precipitate in a glass tube which was narrowed at one end and graduated experimentally. 100 cubic centimetres of urine were placed in a conical flask (Erlenmeyer) of about 250 cubic centimetres capacity; one gramme of lithium carbonate was added and the whole was boiled for three minutes. By this means practically the whole of the phosphates were precipitated as phosphate of lithium and free carbonic acid was eliminated. The liquid was filtered whilst hot to remove precipitated earthy salts, &c., and the filter was washed with distilled water until the filtrate measured 100 cubic centimetres; the filtrate containing the uric acid as lithium urate was then cooled down to 60° F. 50 cubic centimetres of the filtrate were transferred to a flask and five grammes of ammonium chloride were added and the flask was shaken until the salt was dissolved. After standing for three minutes the contents of the flask were warmed to 120° F. to secure a uniform aggregation of the precipitated urate of ammonium and the turbid mixture was now poured into a tube graduated in parts per 100 of uric acid and deposition was allowed to take place, the reading being taken after four hours had elapsed.

DENTAL SURGERY.

FRIDAY, JULY 28TH.

Mr. J. F. COLYER (London) read a paper on

Dental Diseases in Horses.

Mr. Colyer said that he had examined some 500 skulls of horses which had died in London. In 66 cases dental caries was present, in some instances slight and in others causing extensive destruction, as many as ten teeth being affected. The clinical and pathological conditions differed from those seen in the human teeth from the difference in structure, the greater part of the carious dentine being worn away in mastication. Caries was more common in the maxillary than in the mandibular teeth; only three cases of caries were seen in the lower jaw. Although caries was more common in old than in young horses cases did occur in quite young ones. Cupping, unequal attrition, and sometimes one tooth worn almost away were also frequently observed. The appearances generally suggested that the food of the horse had in its composition some ingredients which appeared to cause caries. Peridental disease was common in horses; 166 specimens showed more or less injury to the peridental membrane ranging from slight injuries to the most aggravated form of bone infection, together with occasional infection of the antrum. In these cases the breath of the animal was extremely offensive. When extra molars were present with mal-occlusion peridental disease was marked in their neighbourhood. The peridental disease in the horse appeared to be local in origin and to be due to hard bodies in the diet becoming lodged in the gum or between the gum and the tooth. A consideration of the peridental disease in horses would appear to suggest that the same disease in man was of more local origin than was generally supposed.

Mr. P. SIDNEY SPOKES (London) communicated a paper on

The Teeth as a Test of Age: a Note on Eruption.

He said that it was recently pointed out in THE LANCET that there were numerous practical occasions when the age, usually of a minor, was of forensic interest. The fact might be required for registration purposes (marriage, census returns, or death); for exemption from attendance at school, and under the Employment of Children Act, 1893; for indictments under the Criminal Law Amendments Act, 1895, and the Prevention of Cruelty to Children Act, 1904; for superannuation; and notably in the application of the legal presumptions that a child of less than seven years of age was incapable of committing an indictable offence and could only be punished if under 14 years of age on proof of actual malice. English statutes usually imposed the onus of proof upon the defendant; at the common law in cases of dispute infancy was presumed. Certificates of birth, baptismal registers, and, as with a case in 1808, the receipted entry in an accoucheur's day-book, had all been produced and admitted as valid evidence. There were, however, cases where documentary evidence was not forthcoming; the age of these persons must be presumed. Recent Acts had adopted the principle of facial diagnosis: "Where a child is ...... alleged ...... to be under any specified age and the child appears to the court to be under that age, such child shall, for the purposes of this Act, be deemed to be under that age unless the contrary is proved." The state of dentition might assist and this, Mr. Spokes thought, was the most that they could say. The late Sir Edwin Saunders, in the hope that he might assist in the prevention of the employment of young children in factories, examined the mouths of several hundred children of known ages and was of opinion that from their great uniformity of configuration, size, and arrangement the teeth possessed characters more definite and constant than any other parts. Their physiological history was consequently more precise and subject to less variation than that of any other organ. His examination of 227 boys, aged 13 years, showed that 25 per cent. of the second permanent molars were absent. In 111 girls 14 per cent. were absent. But he seemed to have adopted the principle of assuming the presence of the fourth when the other three were fully erupted and thought that of the 338 children, 13 years of age, no less than 294 might have been pronounced with confidence to be of that age from the inspection of their teeth. In 49 boys between 12 and 13 years of age, 16 (32 per cent.) had all four second permanent molars erupted; five (10 per cent.) had all four absent. These boys should have accounted for 196 second molars; 32 per cent. of these were fully erupted, 38 per cent. were erupting, and 28 per cent. were absent. Of the latter 34 were missing from the maxilla and 22 from the mandible. Taking, then, the erupted and the erupting together, 71 per cent. of the second permanent molars were visible in the mouths of those boys who had not completed their thirteenth year. In 638 boys between the years of 13 and 14 the percentage of those with all four second molars properly erupted rose to 62, but 4 per cent. had all four absent, 5 per cent. had three absent, 7 per cent. had two absent, and 7 per cent. had one absent. Of the teeth themselves, 62 per cent. were present, 23 per cent. were in process of eruption (making 85 per cent. visible in the mouth), and 14 per cent. were absent. Of 492 boys between 14 and 15 years 404, or 82 per cent., had all the four second molars in place. Only 2 per cent. had all four absent, 2 per cent. had three absent, 3 per cent. had two absent, and 7 per cent. had one absent. 10 per cent. of the teeth were in the eruptive stage, making 92 per cent. visible in the mouth, and 7 per cent. were still absent. The examination of boys over 15 years of age showed that in some cases second molars were absent and others only just showing. In some others the third molar or wisdom tooth was visible. Mr. Spokes said that he was afraid he could not hope to make the enumeration of these figures very interesting but every care was taken to insure accuracy. They must speak for themselves, but he thought they must confess that they were unable to rely entirely upon the teeth as a test of age. In some cases they could say affirmatively that the individual had in all probability reached a certain age. They could not so certainly say negatively that he had not attained a stated age. Certain other conditions of the denture might possibly have to be considered, as, for instance, the previous extraction of the first permanent molar which favoured the earlier eruption of the second molar. Of the missing molars 329 were from the maxilla and 229 from the mandible. With regard to the other permanent teeth, 12 per cent. of canines were absent in those under 13 years of age, 3 per cent. of those under 14, and 1 per cent. in those under 15. Here, again, a large proportion were upper teeth; only 18 lower canines were unerupted. The first bicuspids were more constant, due allowance being made for the removal of some for regulation purposes. 5 per cent. were absent at 12 years of age, 2 per cent. at 13 years, and 0·26 per cent. at 14 years. As might be expected a larger proportion of second bicuspids were unerupted and here the lower ones were most frequently missing. The percentages were: 15 at 12 years of age, 8 at 13 years, and 4 at 14 years. Of course, the presence or absence of all teeth should be taken into account in endeavouring to estimate age.

Dr. E. A. Bogue (New York) read a paper entitled

The Influence on Development of arranging Irregularly Placed Teeth into Normal Positions.

The paper was illustrated with lantern slides. At the outset Dr. Bogue explained that the question of adenoid growths and their influence had been omitted, the paper dealing more especially with the effect produced in the other structures by rendering normal an abnormal dental arch. The normal articulation was first discussed and it was pointed out that slight alterations in the position of the temporary teeth might antedate more grave irregularity in the permanent dentition. When the temporary teeth were lost early the permanent molars travelled forward and occupied a more anterior position than normal, so that early extraction might result in a diminution of the whole arch and of the accessory cavities. There was no such thing as large teeth in a small jaw, the bone being formed round the teeth after the crowns were complete. If the irregularities of the temporary teeth were noted it would be possible to prevent irregularity of the permanent dentition without extraction but by mechanical methods. The growth of the bones would be thus promoted. The results of so increasing the size of the dental arch and the jaw allowed of much better development of maxillæ as well as respiration and articulation. In the examination of many hundreds of aboriginal skulls he found that where irregularities existed in the dental arch there were also abnormalities of development in the maxillæ, palate bones, and sometimes lower sphenoid and ethmoid as well. It appeared, therefore, that by just so much as the permanent teeth were regular in their development and were regularly placed in their arches, so all the sinuses of the maxillæ and facial bones were better developed, the nasal septum became straighter, and the turbinated bones less obstructive.

Mr. Colyer considered that Dr. Bogue placed too much stress upon the influence of teeth in the development of the jaws and adjacent parts. It would rather appear that the development of the nasal cavities, &c., together with muscular development, influenced the position and arrangement of the teeth.

Mr. E. Lloyd-Williams (London) was sure that he only expressed the feelings of the section in thanking Dr. Bogue very heartily for visiting the meeting, for however much he disagreed with non-extraction and expanding methods of treating all irregularities Dr. Bogue's reputation for careful and scientific work was well known and the paper was deserving of attention.

Mr. J. G. Turner (London) and Mr. Mummery also discussed the paper.

Dr. Bogue, in his reply, said he was aware that there were objections to what he had said and it was difficult to demonstrate changes of development in the accessory nasal sinuses; unlimited expansion was, no doubt, an evil. He thanked the section for the reception of his paper.

Mr. D. P. Gabell (London) gave a lantern demonstration of Some Pathological Conditions of the Teeth.

Mr. J. F. Rymer (Brighton) read a paper on

Vegetarianism and its Effects upon the Teeth.

He considered the various diets and their necessary constituents and referred to the deficiencies of diet among the working classes. He also discussed the diet of the more wealthy classes, especially of the children, and pointed out that the more simple constituents and vegetable elements of diet had become in a large measure superseded. He then described an order of monks who were vegetarians with the addition of eggs and fish to whom he was in the habit of rendering professional services. The incidence of ordinary dental caries was very small but there were a good deal of alveolar suppuration and loosening of the teeth.

Dr. Astley V. Clarke (Leicester) read a paper on an Unusual Case of Necrosis of the Jaw occurring in a child two and a half years of age. The case was treated with antistreptococcic serum.

A paper on an Unusual Case of Alveolar Abscess persisting for two years was read by the honorary secretary on behalf of Mr. F. L. Dodd (London).

The President of the section (Mr. Morton Smale), in concluding the proceedings, congratulated the members on the success attained and the meeting terminated with a vote of thanks to the honorary secretaries.

TROPICAL MEDICINE.

Thursday, July 27th.

Dr. J. M. H. MacLeod (London) opened a discussion on

Tropical Diseases of the Skin

by regretting the absence of Dr. Jeanselme of Paris, whose presence they anticipated and hoped for, as he had made the subject of tropical dermatology a special study. Dr. MacLeod arranged tropical skin ailments into four groups: 1. Skin diseases due to some known parasite. Of these, some were due to (*a*) bacteria, such as tuberculosis cutis and leprosy, which were, however, in no way specially tropical; (*b*) streptothrix, of which Madura foot was the best example; (*c*) blastomycetes or yeast fungi which were common infections in the tropics, and recently a variety termed blastomycetic dermatitis had been described in America which, clinically and histologically, bore a certain resemblance to lupus vulgaris of the verrucose type; (*d*) hyphomycetes or moulds of which the many varieties of ringworm were examples, chief amongst which was tinea imbricata, but as the fungi of ringworm varied in Europe so, no doubt, different tropical countries had their own types: the precise fungus in pinta disease was not yet settled; and (*e*) of diseases due to animal parasites they had the world-wide acarus. Craw-craw was said to be associated in some indefinite way with filaria perstans and the pani-ghao or ground itch of Assam was considered by Dalgetty to be due to the larvæ of ankylostoma. Elephantiasis arabum had been ascribed to blocking of the lymphatics by the immature ova of filaria Bancrofti but there was much to be said against the supposition. 2. Diseases in which there was strong evidence of a parasitic origin but in which a specific micro-organism had not yet been established. In this group some kind of micro-organism either of the staphylococcus or streptococcus type seemed to be responsible. The best known were the oriental sore now found to be associated with the Leishman body and the phagedænic ulcer of warm countries. The veldt sore had been stated by Bishop Harman to be due to a diplococcus which he named the micrococcus vesicans. Pemphigus contagiosus was possibly due to a virulent micrococcus of the streptococcal type, keloid to a micro-organism of some kind, and yaws had recently been still further proved to be nearly allied to syphilis inasmuch as a spirochæta had been found in both. Under this group also might be classed ulcerating granuloma of the pudenda. 3. Diseases in which micro-organisms were generally present but were probably secondary factors in the evolution of the disease. Prickly heat and dysidrosis were of this type. 4. Non-parasitic skin affections of the tropics. Pellagra and acrodynia were no doubt due to toxins and pigmentations of the skin, vitiligo, and ainhum had also a place in the category of tropical diseases of the skin.

Dr. F. M. Sandwith (London) read a paper on

Pinta, sometimes termed "Spotted Sickness" and "Carate."

Pinta was defined as a tropical disease caused by a fungus which produced various discolourations in the uncovered parts of the skin and sometimes on the mucous membrane. It belonged to the group of specific skin diseases caused by vegetable parasites. Pinta was endemic in the Republic of Colombia, in Venezuela, Peru, Bolivia, Chili, Central America, Mexico, and British Honduras; isolated cases had been met with in Tripoli, Egypt, and the Gold Coast. Dirt and poverty seemed to be the predisposing agents. Nine varieties of the fungus (trichophyton pictor) were described, the differences consisting chiefly in the colour. The period of incubation was about one month; the eruption was not usually symmetrical and was accompanied by a furfuraceous desquamation. In the first stage of the disease there was active increase of pigment and in the second disappearance of pigment, a pseudo-vitiligo, of which the traces were said to be permanent. The disease might last a lifetime unless treated. The treatment consisted in the application of tincture of iodine and Vleminckx's solution applied to the spots in the early stages but in long-standing cases chrysarobin or nitrate of mercury ointment might be tried.

Dr. L. W. SAMBON (London) read a paper on

Pellagra

and urged the necessity for further investigation of this disease.

Dr. J. CAMPBELL GRAHAM (Deli, Sumatra) contributed

Notes on Frambœsia Tropica

and described two cases he met with in Sumatra in Europeans, one being a Dutch girl, aged four years, and the other a German girl, aged six years. In both cases it was only when the patients reached Europe that the disease disappeared. Frambœsia was scarcely ever seen in Europeans in Java or Sumatra. The Javanese responded to treatment more satisfactorily than did Europeans. Iodide of potassium and mercury with local applications of sulphate of copper were efficient remedies and lately Dr. Graham had met with encouraging results with bicarbonate of sodium given internally.

Dr M. E. JEANSELME (Paris) sent a paper (which was translated and abridged by Dr. SANDWITH) entitled

Notes on Pian (Yaws) met with in French Indo-China.

Dr. Jeanselme did not accept the idea that syphilis and yaws were identical diseases. He tabulated the differences between yaws and syphilis and drew attention to the fact that actinomycosis, as well as yaws and syphilis, was cured by iodide of potassium. Yaws was highly contagious, children especially being liable to become infected. The disease was not hereditary.

Mr. JOHN BELL (Hong-Kong) sent a communication on

A Tropical Skin Disease.

On the sole of the foot of an Indian policeman who had been in Hong-Kong nine years Mr. Bell found a large circular patch with undermined edges. In scrapings of the sore Dr. W. Hunter discovered a parasite which he identified as rhizoglyphus parasiticus, figured in Max Braun's "Die Thierischen Parasiten des Menchen." Treatment with 4 per cent. formalin in glycerin was rapidly successful.

Mr. GEORGE PERNET (London) contributed a paper entitled

Involvement of the Scalp in Leprosy.

The hairy scalp generally escaped in leprosy but Mr. Pernet had met with two exceptions to the rule in England. In lupus also the scalp was seldom attacked, although Mr. Pernet had seen lupus develop on the scalp separately; the dilated vessels coursing over the lupus infiltrations served to differentiate them from syphilomata and lepromata in this situation.

Dr. A. ALDO CASTELLANI (Colombo, Ceylon) sent the following papers:—

(*a*) *On the Presence of Spirochætæ in Two Cases of Ulcerated Parangi (Yaws).*

This communication is most important as it serves to affiliate syphilis and yaws still more closely seeing that a spirochæta has been recently met with by Schaudinn in syphilis. The yaws spirochæta was seen by Dr. Castellani in February, 1905, as an extremely minute and almost invisible organism stainable by the Leishman method.

(*b*) *Observations on the Dhobie Itch and other Tropical Trichophytic Diseases.*

Dhobie was the term applied by the laity in the tropics to any pruriginous skin affection, more especially when the genital regions, the axillæ, or the mammary regions were involved. In scrapings examined in liquor potassæ mycelial tubes and spores were to be seen; the segments of the mycelium were almost straight and had a double contour; the fungus grew slowly on maltose agar. In one patient in whom the disease persisted pure oil of turpentine brought about a cure. In one case met with the trichophyton of Dhobie itch attacked parts of the body other than the usual regions and gave rise to eruptions resembling tinea circinata. Dr. Castellani considered tinea and Dhobie itch as distinct diseases; the fungi of each differ and the fungi in tropical tinea were of various species and possibly differed from those met with in Europe. Dhobie itch and tinea circinata might occur in the same persons but on different regions of the body. Tinea imbricata due to the trichophyton Mansoni occurred in Ceylon. Ringworm of the scalp due to the trichophyton megalosporon endothrix was occasionally met with in Ceylon.

(*c*) *Tropical Forms of Pityriasis Versicolor.*

There were several forms of pityriasis versicolor met with in Ceylon. Two principal types might be distinguished: one black, pityriasis versicolor nigra; and one yellow, pityriasis versicolor flava. As regards the microscopical appearance of the fungi, that of pityriasis versicolor nigra was very abundant and had a mycelium of rather large size and very large spores which ran in clusters. Of pityriasis versicolor flava there were two varieties; one met with on the face, the neck, and the upper part of the trunk presented but few fungi, the mycelium being thick, irregular in shape, the spores few, not large, nor running into clusters. In the second variety of pityriasis versicolor flava the mycelium was found to be thin and regular in outline and the spores were very numerous, small, oval, and might be grouped in clusters. Judging from a few cultures made the fungi appeared to differ in their characteristics culturally.

Dr. KARL GROSSMANN (Liverpool) showed coloured photographs of Icelandic lepers by lantern slides, directing attention more especially to the condition of the eyes and palpebral surroundings.

In the discussion which followed Professor R. W. BOYCE (the President of the section), Dr. H. RADCLIFFE CROCKER (London), Major G. H. FINK, I.M.S., Dr. A. J. CHALMERS (Ceylon), Dr. SANDWITH, Dr. C. F. HARFORD (London), Dr. D. E. ANDERSON (Paris), and Mr. J. CANTLIE (London) took part.—Dr. CROCKER, discussing Dr. MacLeod's paper, pointed out the unsatisfactory state of the pathology of elephantiasis arabum and the confusion in regard to the varieties of ringworm. He also described a case of granuloma in the groins in a negro who had resided in London for many years.—Major FINK said that oriental sore was known by a variety of names in India. The idea prevailed in some parts of India that persons who suffered from oriental sore were believed to be rendered more or less immune to malaria. Major Fink also showed photographs of microscopic flagellates obtained from oriental sores which he had examined and of sand flies which he had collected with flagellated organisms like parasitic cercomonas in their interior.—Dr. SANDWITH, dealing with the relation of maize infected by weevils to pellagra, stated that he did not consider weevils the direct cause of pellagra in man, though it was true that weevils and mould often infected the maize side by side. The female weevil pierced the grain with its snout in order to make a convenient hole to lay its eggs in; it was therefore obvious that its could easily introduce inside the grain (which might be afterwards eaten by man) any spores of a fungus which happened to be outside the grain.

THE ANNUAL EXHIBITION.

V.—MINERAL WATERS, BEVERAGES, ETC.

MINERAL waters and beverages were not strongly represented and those shown belonged to the class of natural waters. The water derived from Vittel in the Vosges deserves attention, since it has gained reputation in the treatment of gouty disorders and urinary diseases. The water is not highly mineralised, is "clean" to the palate, and slightly alkaline. There are three springs at Vittel, the waters of which vary slightly as regards their mineral contents and two of them are ferruginous. Vittel contains all the usual appointments of a hydrothermal establishment. Another interesting natural mineral water from France, but without claims to any particular medicinal value, is Perrier, which contains its own natural carbonic acid gas associated with small quantities of carbonates. The water is agreeable to the palate and well adapted for table purposes. Apollinaris water and Johannis water are, of course, well known and samples were exhibited in by the Apollinaris Co., Limited, of 4, Stratford-place, Oxford-street, London, W. Samples also of Apenta from the natural bitter water springs near Budapest were shown. The waters of the State springs of Vichy were illustrated in the exhibit of Messrs. Ingram and Royle, Limited, of East Paul's Wharf, 26, Upper Thames-street, London. Samples also were shown of natural Carlsbad salts and Contrexéville water from the Pavilion springs. The waters of Buxton, Harrogate, and Leamington, together with photographs illustrating the hydropathic equipments at these places, were exhibited by the Buxton urban district council and the Harrogate and Leamington corporations respectively. Lastly, Messrs. C. Oppel and Co., of 10 and 12, Milton-street, London, E.C., exhibited samples of Friedrichshall water, which belongs to the pure bitter saline class of natural waters.

VI.—PUBLICATIONS.

The only publishers exhibiting were Messrs. W. B. Saunders and Co. of 9, Henrietta-street, London, W.C. (medical hand atlases and new surgical and medical works), and Mr. H. K. Lewis of 136, Gower-street, London, W.C. (practical series and the New Sydenham Society's publications).

VII.—MISCELLANEOUS.

The miscellaneous section of the exhibition chiefly comprised motor-cars designed more or less for the use of the medical man. The Clyde Motor Co., Limited, of Leicester, showed a Clyde 7–8-h.p. doctor's car, and besides a three-seated tonneau car and a Clyde 6-h.p. tricar. The Ryknield Engine Co., Limited, of Burton on-Trent, exhibited a well-designed car called the "Doctor's Landaulette," with 15-h.p. vertical engine and three separate cylinders. The Polymobile Co., of 6, Christopher-street, London, E.C., brought to the notice of the visitors a special car which has been designed for the medical practitioner. The Anglian Motor Co., Limited, of 78, Brompton-road, London, S.W., showed their Anglian light car and a tricar fitted with two speed gear and a motor bicycle. The Humber Co., Limited, of Coventry, exhibited their well-known Humber four cylinder touring car as well as three light cars. Lastly, Mr. S. J. Lilley, of Welford-place, Leicester, exhibited a motor-car and a medical brougham of excellent design, and the Central Motor Car Co., Limited, of 117, Long Acre, London, showed two examples of a 10-h.p. Ford car, one of which is provided with an attachable "tonneau," making the car "four-seated" or two-seated at will. Opportunities were afforded during the meeting of making trial runs in some of the cars exhibited.

THE PATHOLOGICAL MUSEUM.

THE Pathological Museum in connexion with the annual meeting of the British Medical Association, although itself of wide and varied interest, has undoubtedly gained enormously this year by being situated under one roof with all the sectional meeting rooms. Indeed, we have never before seen the museum utilised to such an extent or by so many visitors as in the present instance or the removal of individual specimens from the museum for the purpose of illustrating members' communications and discussions in the sections so readily carried out. The numerous exhibits comprised wet specimens, dried preparations, water-colour and oil paintings, photograms, skiagrams, microscopical preparations, and a large variety of lantern transparencies, both in monotone and in colours, and they were arranged in conspicuously labeled divisions to correspond with the various sections, so that it became an easy matter to find the exhibits relating to any particular subject.

The large room on the first floor of the technical school's in which the museum was housed was divided by partitions into three nearly equal compartments, one of which, that to the right of the entrance, was entirely filled by the exhibits of the gynæcological section. This exceedingly fine collection of specimens, &c., was, we understand, secured chiefly by the efforts of Dr. Louisa Garrett Anderson, one of the secretaries of that section. Grouped with consecutive numbering, the specimens illustrated extra-uterine gestation, degeneration of fibroids, malignant disease of the uterus, adenomyoma of the uterus, and a group of miscellaneous specimens, the most striking of which were full-sized sections of the pregnant tube and uteri showing cancer, tubercle, &c. The pathology of extra-uterine gestation was fully illustrated by drawings and sections from a case of ovarian pregnancy shown by Dr. Catherine van Tussenbroek of Amsterdam, and by an excellent series of sections, drawings, and slides shown by Dr. G. H. A. Comyns Berkeley and Dr. W. F. Victor Bonney. The group of specimens showing the degeneration of fibroids was particularly complete, the largest number and most interesting of the exhibits being contributed by Dr. S. J. Cameron (Glasgow), Dr. A. Leitch (Glasgow), and Mr. C. J. Bond (Leicester). Another exhibit in this group that attracted considerable attention was a series of 15 photographs illustrating degenerations of fibromyomata prepared by the Sanger-Shepherd three-colour process—the work of Miss A. Debenham.

The exhibits of the Section of Pathology occupied the central compartment of the museum and a portion of that to the left of the entrance and included many of more than passing interest. Immediately within the doorway was arranged a series of delicate little water-colour sketches lent by Dr. F. W. Mott (London) illustrating trypanosomes in blood-vessels of the central nervous system of animals, microscopical appearances of the lesions in sleeping sickness and in various forms of meningitis, &c., which bore high testimony to the skill and fidelity of the artist, Miss Kelly. Equally noteworthy was an extensive series of specimens illustrating the naked-eye appearances of leucoblastic and erythroblastic conditions of the bone marrow associated with various diseases, acute and chronic, and supplemented by a series of photomicrographic representations of bone marrow obtained from animals as well as from the human subject. These were exhibited by Dr. W. E. Carnegie Dickson (Edinburgh). Mr. Richard Muir (Edinburgh) showed a splendidly executed set of black-and-white drawings of pediculi and micro-photo transparencies illustrating the life-histories of trematode, cestode, and nematode worms and of malarial parasites. Not far off were to be seen embryo nematodes and the newly described *schistoma Cattoi* exhibited by Dr. J. Catto. Mr. W. Sampson Handley (London) showed a series of drawings, photographs, and microscopical preparations, illustrating by means of sections through the growing edge the theory that permeation is the principal factor in the dissemination of mammary cancer, and Mr. Bond (Leicester) had arranged a comprehensive series of photographs of uterine and ovarian physiology and pathology in the rabbit. Perhaps the exhibit which produced most comment was that shown by Mr. C. C. Hurst, F.L.S. (Burbage), consisting of specimens of peas, sweet peas, orchids, rabbits' pelts, and diagrams of domestic fowls and their combs, illustrating the principal point of Mendel's law of heredity—viz., the separate inheritance of single characters and the segregation and gametic purity of such characters after crossing.

The exhibit of the Section of Medicine was a small one but included an interesting series of wet specimens shown by Dr. R. A. Bolam (Newcastle-upon-Tyne) of aneurysm of the left ventricle and a number of photographs and skiagrams from cases of acute and chronic joint disease lent by Dr. Bertram L. Abrahams (London). A number of radiographs and some striking painted photographs of rodent ulcer and x ray dermatitis by Mr. J. Hall-Edwards (Birmingham) were placed in the Section of Surgery, together with an extensive set of radiographs of foreign bodies, stones, fractures, and deformities by Mr. C. Thurstan Holland (Liverpool). The Section of Navy and Army was occupied by an extremely interesting collection by Fleet-Surgeon C. Marsh Beadnell, R.N., of Lee-Enfield, Lee-Metford, Remington, and Mauser cartridges, bullets; various articles of clothing and materials showing bullet apertures and a series of Filippino skulls illustrating bullet wounds. To complete this series Mr. Lynn Jenkins (Hinckley) had lent a collection of shells and bullets from South Africa. The exhibit of the Section of Tropical Medicine was small also, the chief feature being the set of original drawings shown by Dr. J. H. MacLeod (London), illustrating the histo-pathology of yaws, lepra, syphilis, &c.

ST. PETERSBURG LADY PRACTITIONERS AND OPHTHALMOLOGY.—The Women's Medical Institute has again requested a subsidy from the St. Petersburg town council for the founding of an eye clinic. A similar request previously made had been refused but the need is so urgent that this time it is expected that the council will consent on the condition that the clinic is opened for the St. Petersburg population in accordance with the requirements of the town medical adviser.

THE LANCET.

LONDON: SATURDAY, AUGUST 12, 1905.

"Earth Temperature and Diarrhœal Diseases."

THE seasonal variations in the incidence of many acute and epidemic diseases are well recognised and have long exercised the minds of clinicians, hygienists, and bacteriologists. Much speculation has arisen and not a few experiments have been carried out with the object of throwing some light upon the relationship existing between meteorological and telluric conditions and the incidence of these diseases. So long ago as 1855 Dr. EDWARD SMITH published a paper[1] in which the conditions of atmospheric temperature, rainfall, and other climatological factors were carefully considered in relation to the outbreak of cholera in London in the previous year. Some years afterwards Dr. EDWARD BALLARD published a series of papers[2] in which he examined the influence of weather and season upon public health after a statistical study of 217,000 cases of disease occurring during nine years. The importance of the nature and the condition of the soil in relation to the occurrence of some bacterial diseases was also early recognised and studied by Sir GEORGE BUCHANAN, Dr. BOWDITCH, and Professor PETTENKOFER. In no group of diseases is the relationship between incidence and meteorological conditions more marked than in that which comprises cases of diarrhœa and acute gastro-enteritis. It has long been recognised that a hot, dry summer is associated with a larger number of cases and a heavier rate of mortality than a cool or wet one. The relationship was investigated by Dr. BALLARD and an exhaustive report was presented by him to the Local Government Board in 1887. Among many other inquiries he compared the curve of incidence of diarrhœal diseases in London and other towns with those of the temperature of the earth at depths of one foot and four feet below the surface respectively. His main results may be briefly summarised as follows. The summer rise of mortality due to these diseases does not occur until the temperature of the soil four feet below the surface reaches the level of 56° F. and the maximum mortality occurs in the week at which the temperature of the soil at the four-feet level attains its mean weekly maximum, while the decline of diarrhœal mortality coincides with the decline of the temperature of the soil at that level and does not follow the curve of the temperature of the atmosphere or of the soil at a depth of one foot.

These observations have been extensively quoted in various monographs and text-books but few attempts seem to have been made to put them to the test or to investigate the nature of the connexion between the two series of records. A paper has recently been published[3] by Sir JOHN W. MOORE on Earth Temperature and Diarrhœal Diseases in Dublin in 1904, in which this relationship has been tested by him in conjunction with his son, Mr. A. R. MOORE. Although the observations deal with one year only, owing to the fact that a climatological station was not installed at the University of Dublin until Jan. 1st, 1904, yet the results obtained are of considerable interest and confirm in the main those previously recorded by Dr. BALLARD. It was found that the diarrhœal mortality in the Dublin district was very small until the third week after the temperature of the subsoil at a depth of four feet had passed the critical level of 56° F., while the maximum mortality followed a fortnight after the maximum temperature. This fortnight of latent period or delay Sir JOHN MOORE attributes to the time occupied by the progress of the cases to the fatal issue and in the subsequent registration of the deaths. This seems to us in view of the rapidly fatal character which the disease frequently assumes to require verification which is, however, a matter of some difficulty, since the duration of the fatal illness is rarely recorded upon the certificate of death. It was further found that the four-feet earth thermometer stood at 56° F. or upwards for 11 weeks—namely, from July 10th to Sept. 24th. Taking a period of 11 weeks, dating from a fortnight later to allow for the period of latency—that is, from July 24th to Oct. 8th—the striking total of 249 deaths was found to have occurred, which is 71·7 per cent. of the total mortality from diarrhœal diseases for the year—namely, 339.

Dr. BALLARD, in the report to which reference has already been made, deduced the following conclusions from his observations. The essential cause of epidemic diarrhœa resides ordinarily in the superficial layers of the earth where it is intimately associated with the life processes of some micro-organism which is dependent among other things upon conditions of season and on the presence of dead organic matter which is its pabulum. On occasion this micro-organism is capable of becoming air-borne and infecting food and there finding conditions favourable to its development; and during development it leads to the production of a virulent chemical poison which is, in the human body, the material cause of epidemic diarrhœa. It is impossible not to admire the ingenuity and the far-sighted character of these deductions and it may be confessed that after a lapse of 18 years there is little to add to them. Most of them have been amply confirmed. Even now, however, our knowledge is far from complete with regard to the bacteriology of these cases, since such various organisms as Klein's bacillus lactis aerogenes, the bacillus coli and its congeners, and the bacilli of dysentery of Flexner and Shiga have all been isolated from cases of this nature. Probably it will be found that there is more than one exciting cause of diarrhœa of epidemic character. The relations between the growth of certain pathogenic bacteria in soil and the conditions of the soil itself have been the subject of investigation in this country by Dr. SIDNEY MARTIN and Dr. A. C. HOUSTON. Dr. MARTIN[4] has carefully studied the growth of the typhoid bacillus and has found that in certain virgin soils it neither lives nor grows but after cultivation such soils when sterilised become capable of maintaining the bacillus for a limited time. On the other hand, cultivated soils when unsterilised are inimical to the growth of typhoid bacilli which disappear in about 12 days after being placed in them. Dr. MARTIN concluded that the disappearance of the typhoid bacillus was probably due to the deleterious action on its growth of the products formed by the bacteria natural to the soil. Dr. HOUSTON has further investigated the question[5] and has found that if sewage be added to garden soil there is only a temporary increase of sewage microbes at the expense of the soil microbes, the latter eventually ousting the former, and also that pathogenic bacteria do not maintain their vitality for more than a brief period in the superficial layers of the soil. A further point of some interest, clearly brought out in Sir JOHN MOORE'S charts, is the influence of rainfall in diminishing the mortality of diarrhœal diseases. On two occasions during the epidemic period a rainfall of an inch or upwards was followed after a fortnight's interval by a definite fall in the mortality. According to Dr. A. NEWSHOLME rainfall is of more importance than temperature in relation to this disease. The whole subject of the relation of disease-producing organisms to meteorological conditions in the widest sense is one which offers a great field for future work, with the promise of results of far-reaching importance; and we welcome the interest which has been aroused in this matter in the United Kingdom.

◆

The Control of Proprietary Remedies.

A SERIOUS attempt is being made by the Council of Pharmacy and Chemistry of the American Medical Association to control the various secret remedies which are put before the medical profession in that country. The following particulars of the scheme are taken from a copy of the rules for which we are indebted to the courtesy of a well-known firm of druggists. It appears that in the United States of America there is a rapidly growing sentiment against the increasing legion of secret preparations. The *Journal of the American Medical Association* conceived the idea of forming a board of control, to be composed of pharmacists and chemists, which should pass in review all medicinal preparations offered for insertion in the advertising pages of that journal. That idea has been modified by making the functions of the proposed board similar to those of the Committee of Revision of the United States Pharmacopœia. The work is to be taken up where that committee left off and a description of the unofficial preparations which conform to the required standard will be published in the form of a book to be entitled "New and Unofficial Remedies." In other words, it will form an extra pharmacopœia giving useful details of reputable preparations. The board of trustees of the American Medical Association has authorised the formation of an advisory board, to be known as the Council of Pharmacy and Chemistry, to carry out the work. The council is composed of men eminent in medicine and pharmacy as writers, teachers, and research workers. The council proposes immediately to examine into the composition of the various medicinal preparations that are offered to physicians and are not included in the United States Pharmacopœia or in other standard text-books or formularies. In the rules here given the term "article" is applied to any drug or preparation used in the treatment of disease.

RULE 1.—No article will be admitted unless the names of the active ingredients and the strength be given for publication. It is considered the duty as well as the right of the physician to know the composition of medicines which he prescribes for his patients. No one would voluntarily call in a physician who was in the habit of prescribing remedies the constituents of which were not known to him. The published statement will in some instances give the general character of the vehicle and flavouring agents, and in the case of preparations intended for external use the character of the vehicle or base must be stated in order to indicate whether the article has penetrative or simply protective properties.

RULE 2.—No chemical compound will be admitted unless information be furnished regarding tests for identity, purity, and strength, and in the case of a synthetic compound the rational formula must be given.

RULE 3.—No article that is advertised to the public will be admitted, excepting disinfectants, cosmetics, foods, and mineral waters, when such articles are advertised in an unobjectionable manner.

RULE 4.—No article will be admitted bearing the names of diseases in the treatment of which the article is indicated but the therapeutic indications, properties, and doses may be stated. This rule does not apply to vaccines and antitoxins, nor to advertising in medical journals, nor to literature distributed solely to physicians. This rule is framed with a view of stopping the practice of self-drugging, and is in the interests alike of the laity and the profession. The laity are not competent to determine whether the employment of a given article is safe and proper, and they are often induced to continue its use or to recommend it to others quite regardless of the evident dangers of forming drug habits or of doing serious injury by employing a remedy that in reality may be contra-indicated. It is the prerogative of the physician alone to determine in what disease a given article may be indicated.

RULE 5.—No article will be admitted or retained about which the manufacturer or his agents make false or misleading statements regarding the country of origin, the raw material, or the method of collection or preparation.

RULE 6.—No article will be admitted or retained about whose therapeutic value the manufacturer or his agents make unwarranted, exaggerated, or misleading statements.

RULE 7.—Labels on articles containing poisonous substances should show the amounts of each of such ingredients in a given quantity of the product. This information enables the pharmacist to safeguard the patient and physician.

RULE 8.—Every article should have a name indicative of its chemical composition or pharmaceutical character in addition to its trade name, when such trade name is not sufficiently descriptive.

The manufacturers of legitimate preparations have nothing to fear from this action on the part of the American Medical Association. On the contrary, they are to be congratulated that the Association has undertaken to separate the wheat from the chaff. In this country medical practitioners are overwhelmed with samples and literature of preparations which may be good, bad or indifferent. The composition is not usually disclosed and the habit is formed of throwing all aside, the good and the bad together. The list of unofficial preparations of known composition and strength when published by the American Medical Association should prove valuable to the medical profession and a safeguard to the public. Measures of similar character might with advantage be adopted in this country. It should not be difficult to find funds for the purpose, especially if a working arrangement were made with the American Medical Association whereby each country should investigate its own products to avoid covering the same ground twice.

---

[5] Reports of Medical Officer to Local Government Board, 1898–1902.

Though the rules adopted by the American Medical Association are good and worthy of imitation they are not sufficiently comprehensive to nullify entirely the present system which leads to self-drugging. The weak points are not hard to find. Let it be imagined that a practitioner prescribes a preparation which is labelled on the lines laid down in the rules, as follows: "A hypnotic and sedative, containing three-quarters of a grain of morphine in 110 minims. Dose 5 to 30 minims." Unless the practitioner initials and dates the prescription whenever he requires it to be repeated there is nothing to prevent the repetition of the prescription dozens and even hundreds of times. Pharmacists should be requested to consider it a breach of etiquette to copy a prescription for a patient or to make it up for any other person. Again, it should be a rule that no proprietary medicine should be delivered to the patient in the original package in order to prevent the purchase of further supplies without a prescription. The excellent rules of the American Medical Association should therefore be supplemented by further rules for the guidance of pharmacists on these points touching the repetition of prescriptions and the transference of medicines from original packages before delivery to the patient. A set of rules of this kind, supplemented by a more complete code of pharmaceutical etiquette, would benefit alike the public and the medical profession and should find a place in the system of medico-pharmaceutical ethics.

Again, it is obvious that another weak point in the proposed scheme is that it will almost of necessity fail to touch the very class of secret or proprietary remedies which are productive of the largest amount of self-drugging—viz., so-called "patent" medicines produced for the express purpose of appealing to the credulity of the multitude. Since the proposed list is rightly intended solely for the use of medical men the failure to secure recognition will hardly be of any material detriment to the sale of such preparations which will still be advertised in the lay journals and reach the public for whom their proprietors cater.

◆

The Prevention and Treatment of Anthrax in Man.

The danger of infection from anthrax incurred in the handling of wools, hides, and horsehair, especially in the sorting and preparation of imported supplies from certain foreign districts, has long been recognised in this country and the popular name of "wool-sorters' disease" frequently applied to some of these infections is an evidence of this. To endeavour to deal with this matter and to minimise the risk of infection the processes of sorting, willowing, washing, combing and carding wool, goat hair, and camel hair have been classed as dangerous and included within the provisions of the Factory and Workshop Act, 1901, and all cases of anthrax contracted in connexion with such industries must be reported to the Home Office. After a detailed discussion at Bradford by a joint committee, to which representatives of both masters and men were invited, a draft series of regulations has been issued by the Home Secretary and transmitted to those whom they concern, with an accompanying letter dated July 13th, stating that if objections of substance are taken to them either by the occupiers or the workpeople, or by any other persons affected, these objections, which must be addressed in writing to the Home Secretary, together with the specific grounds of objection, will be the subject of full inquiry by a competent person appointed by the Home Secretary before the final regulations are made. At this inquiry employers, owners, occupiers, workpeople, and all others concerned will be entitled to a full hearing.

The draft copy of the regulations contains a short note describing in simple terms the character of the disease and the probable channels and methods of infection, such as by breathing or swallowing the dust from infected wools or hairs or by such dust lodging in a cut or scratch or in the cracks of chapped hands. The proposed regulations deal especially with the opening, sorting, and willowing of wool and hair, which for this purpose are classed under three schedules. Schedule A comprises Van mohair, Persian locks, and Persian, or so-called Persian (including Karadi and Bagdad), if not subjected to the process of sorting or willowing; all in this class must be thoroughly steeped in water while in the bale before being opened. Schedule B includes alpaca, pelitan, East Indian cashmere, Russian camel-hair, Pekin camel-hair, and Persian, or so-called Persian (including the two above named), if previously sorted or willowed; hairs and wools in this class may either be opened after steeping or over an efficient opening screen with mechanical exhaust draught in a room set apart for this purpose. Schedule C simply includes all mohair other than Van mohair; these need not be opened over a screen but must be sorted over a board provided with a downward draught. It is further ordered that all opening and sorting shall be carried out by men skilled in judging the condition of the material and that 1000 cubic feet of space shall be allowed for each person in each sorting room and that there shall be efficient ventilation. All pieces of skin, scab, clippings, or shearlings shall be removed daily and disinfected or destroyed, and detailed regulations are proposed for dealing with the dust extracted by exhaust draughts and for the supply of respirators and overalls to be worn by all persons engaged in collecting and removing the dust. The floor of every room where opening, sorting, or willowing is carried on is to be sprinkled with disinfectant solution daily and to be swept immediately after sprinkling; the walls and ceilings are to be cleansed and lime-washed regularly. Suitable washing accommodation and rooms for meals are to be provided away from the sorting and willowing rooms. No person with an open cut or sore is to be allowed to work in the rooms and requisites for treating scratches and slight wounds are to be kept at hand. These regulations seem to represent a very fair and equitable attempt to deal with a difficult problem and we may express the hope that the owners and the men concerned will loyally support the measures recommended, the more so that they have been carefully consulted in these preparations and still have opportunity for suggesting improvements or alterations.

To prevent infection by horsehair and by hides and skins seems, if anything, a more difficult matter, since even steam disinfection or boiling of horsehair cannot be absolutely relied on, while in the case of hides the anthrax spores resist even the action of the fluids used in tanning and it is difficult, if not absolutely impracticable, to disinfect hides which have to be tanned subsequently. Unfortunately, the most rational method of dealing with the problem, that of preventing the importation of infected wool, hair, and hides, is a counsel of perfection which is unattainable. For much valuable information on the subject of infection from anthrax in relation to industrial processes we are indebted to the valuable Milroy lectures delivered before the Royal College of Physicians of London by Dr. T. M. LEGGE, His Majesty's medical inspector of factories.[1] Dr. LEGGE deals especially with the 261 cases reported to the Home Office during the six years 1899–1904. Of these 88 occurred worsted- and wool-workers, 70 in workers with horse-ir and bristles, 86 in those engaged with hides and skins, d the remaining 17 in those engaged in miscellaneous cupations, such as horn-workers, rag-sorters, and porters. he cases infected through wool occurred almost entirely in e Bradford district of the West Riding and in Worcesterire, the reason being that in these places the dangerous lasses of wool are used, while colonial wools, which are ree from infection, are used elsewhere. On the other and, cases due to horsehair are more general in their distribution, while those due to hides and skins occur mainly n London and Liverpool. Cases of anthrax also occur mong persons coming in contact with infected live cattle r engaged in slaughtering or in the disposal of the arcasses, but it is difficult to obtain statistics of these, except of the fatal cases. Dr. LEGGE's figures, however, show that since 1899 the majority of the fatal cases (55 out of 72) have occurred in association with factories or workshops. Among the 261 cases investigated by Dr. LEGGE there was a mortality of 25·6 per cent., which agrees very closely with the rate of 24·1 per cent. among 34,052 cases occurring during the 11 years 1889–1900 in Italy, where the disease is notifiable. It is of interest to notice the source of the materials to which these 261 cases have been attributed. No single case has been traced during the whole six years to wools imported from Australia and New Zealand, although the amounts are very large, the value in 1902 of such imports being estimated at over £13,500,000, whereas at least 30 cases and possibly 40 occurred from Persian wool, the value of which in 1902 was only a little over £13,000. Apparently the reason there is a demand for Persian wool is due to the fact that the Persian breed of sheep is one of the few in which the wool is naturally of a black, brown, or fawn colour. In regard to horsehair the infected supplies seem to come chiefly from Russia and China—in fact, some observers maintain that all bales of mane hair from China should be regarded as infected.

In regard to the prevalence of anthrax its occurrence in animals offers some difficult problems for discussion. Anthrax is a not uncommon disease of animals in all parts of the world; in Great Britain during 1903 there were 1143 cases. The incidence of anthrax shows some peculiar seasonal variations which are different in different countries, the probable explanation being the variations produced by seasonal changes in the conditions favouring the growth of the organism outside the body. There is no doubt that animals have been infected by the refuse from factories in which raw animal products are dealt with but it is probable that many cases are due, as suggested by Professor J. McFADYEAN, to artificial manure and imported foodstuffs, which it has been shown may be carriers of the infection. Again, infection may occur from other cases of the disease or from the careless treatment and disposal of the carcass of an animal dead from the disease. The treatment adopted in human cases, in which the disease is usually local, cases of internal anthrax being rare nowadays, has until recently consisted in simple surgical procedures, such as excision or cauterisation or of subcutaneous injections of weak carbolic acid solutions, while some surgeons have applied powdered ipecacuanha to the wound and have administered the same drug internally. Since 1897, when Professor SCLAVO of Siena first introduced his anti-anthrax serum, widely extended trials of the serum treatment have been made and, according to Dr. LEGGE, who has devoted particular attention to this matter, it is claimed that even in large doses the serum is innocuous, that no case is fatal if serum is given in an early stage, that some apparently hopeless cases have been saved by it, that it reduces the destruction of tissue to a minimum, and, lastly, that in internal anthrax it is the only treatment affording any hope. After injection of the serum there is usually a rise of temperature, often above 105° F., which Professor SCLAVO regards as of favourable prognostic import. The mode of action of the serum is at present the subject of some controversy; Professor SCLAVO regards its main effect as that of stimulating the defensive activities of the phagocytes. It is certainly rather an antibacterial than an antitoxic action. During the past year SCLAVO'S serum has been used in this country and cases have been recorded[2] with encouraging results and afford us some grounds for hoping that the present mortality-rate of 25 6 per cent. may be very considerably reduced. It is of interest to note that in Santa Croce, an Italian town with a number of tanneries, the workers practically insist on having the serum treatment and being now no longer in fear of operation present themselves for treatment at an early stage of the disease.

POLISH DEATH CERTIFICATES IN RUSSIAN.—According to the *Kur. Lodz*, Dr. Grosglika has protested against the requirements of the Warsaw Medical Department that certificates of death submitted as to insurance or for permission to remove bodies should be in Russian. His protest has been reinforced by that of 96 other medical men of Warsaw and a number of lady medical practitioners.

Annotations.

"Ne quid nimis."

THE WORK OF THE GOVERNMENT LABORATORY.

The report of the principal chemist of the Government laboratory generally affords interesting reading and the one recently issued is no exception. The total number of analyses and examinations made in the laboratory in Clement's Inn Passage during the year ending March 31st, 1905, was 88,757. It is obvious that the work must relate to many diverse substances and must therefore require knowledge and experience in almost all the branches of chemical analysis. We are therefore disposed to suggest that the Government might see its way to publish a book on the analytical methods employed in its laboratory. Such a book would not only lead to the adoption of uniform methods of analysis and so avoid controversy based on different methods employed but would be of the greatest value to the general analyst. We commend this suggestion to Dr. T. E. Thorpe, the able principal of the Government laboratory. The laboratory returns this year afford additional evidence of the fact of the reduced consumption of alcoholic beverages, since the number of samples of beers, wines, and so on, examined was considerably less than in the previous year. It is interesting in passing to consider the causes of the decided decline in the consumption of alcoholic beverages. It would appear that this consumption bears some relationship to the prosperity of the country. In prosperous times the consumption increases so that doubtless diminished spending power is a factor, while we think that the recent revelations in regard to the practice of substitution in the wine and spirit trade, in which we have taken a share, have made an undoubted impression upon the public. Owing to the recent proceedings in the police courts against vendors of brandy not made exclusively from the juice of the grape there has been an increase in the number of such samples referred to the laboratory and 13 cases were referred to the Government chemists under the Sale of Food and Drug Act. We are glad to find that the Government chemists were able to sustain the charge of adulteration in regard to 11 of the samples. Our satisfaction is due to the fact that the Government chemists evidently agree with us that chemical analysis does throw light on the question as to whether brandy is or is not made from grape juice. We note that grape juice is admitted free of duty provided that it is genuine and free from spirit. This concession seems to us to encourage the production of wines, the so-called basis wines, in this country which thus escape the duty that is levied on imported wines. This seems to be not only unfair to the importers of wine in this country but to be calculated to give rise to a fraudulent practice. There is no doubt that large quantities of grape juice are imported into this country and fermented into wine which is afterwards sold as genuine Bordeaux wine. There has been a decided increase in the number of samples of tea examined owing, no doubt, to the increased duty on tea resulting in larger importations of lower grade qualities. In regard to the examination of beer there is shown to be a marked diminution in the amount of arsenic found in the materials used in the brewing of beer as compared with the last official year. Butter continues to be imported into this country containing boron preservatives but, as Dr. Thorpe points out, there is a difficulty in restricting this admixture so long as a legal limit is lacking. But why should a legal limit be lacking since we gained the definite pronouncement of a departmental committee on this question some years ago? Under the Sale of Food an Drugs Act 105 samples in all were examined and in ten o these, or 9·5 per cent., the Government chemist's conclusion differed from the public analyst as against 14·4 per cent. las year and 15·2 per cent. for the previous year. It is eviden that the work of the public analyst in this country is reachin a higher standard in each succeeding year.

THE HOSPITAL SUNDAY FUND.

It is now possible to calculate fairly closely the resul of the thirty-third annual collection on behalf of the Metro politan Hospital Sunday Fund, which took place last June The amount actually received at the Mansion House up t date, including Mr. Richard Herring's generous contributio exceeds £75,000, and in all probability another £3000 will b received before the close of the financial year of the Fund o Oct. 31st next. It was hoped that the much-coveted sum o £100,000 would have resulted from the collection this year but bearing in mind the many generous contributions whic have been made to King Edward's Hospital Fund, and the many appeals which have been made for financial suppor for individual hospitals, the collection of £78,000 as a result of the appeal of the Metropolitan Hospital Sunday Fund for 1905 is by no means an unworthy effort and i some £14,000 more than any total that has been previousl collected. On behalf of the suffering poor of our London hospitals we thank all those who have so generously contributed to this gratifying result.

RED RUBBER.

In our issue of June 10th we published a letter from Mr. F. A. Pond of Liverpool drawing attention to the amount of antimony contained in red rubber and to the possibility of a connexion between the use of red rubber rings in bottles of effervescing beverages and food materials and the occurrence of cases of appendicitis and other intestinal disorders. In commenting on this communication[1] we pointed out that the antimony in red rubber is with great difficulty dissolved out of it and after careful trials we could find no evidence that any such solution occurred in the fluids ordinarily kept in the bottles. At the same time we considered the use of rubber of this character for the purpose as undesirable. We have received from a correspondent a copy of the *Wochenschrift für Brauerei* of July 22nd containing an article criticising Mr. Pond's conclusions in very much the same sense. It is there stated that the antimony in red rubber is almost insoluble in organic acids, such as 10 per cent. acetic, but is soluble in hydrochloric acid. On the other hand, there is no evidence of its being dissolved by beer, conserves, or drinks containing fruit juices. The statement that small particles of the rubber become detached and swallowed is also looked upon as very improbable, since particles of cork, which are more frequently found in beverages kept in bottles, are rarely swallowed, and even if small particles of rubber should reach the stomach it is unlikely that the digestive juices would be capable of exerting any solvent action upon them. The writer of the article regards it as noteworthy that in Mr. Pond's series of cases the beverages used were for the most part non-intoxicating or non-alcoholic in character and suggests that since antimony is not dissolved by them some constituent of the fluids themselves may be responsible. He offers the suggestion to medical men that the saponin preparations frequently used to induce frothing of temperance beverages may be the cause of the sequence of events occurring in such a series of cases as that observed by Mr. Pond, since Kobert[2] has recorded weakness and paralysis of muscles following the administration of saponin ies. Coming from a brewing journal and being printed arger type, the suggestion looks not unlike hoisting the otaler with his own petard but it is made in all serious- s. The article concludes with the statement that rubber nufacturers can easily produce rubber rings free from imony and yet of equal value to those at present in use. may add that we have received a further communica- n from Mr. Pond in which he points out that the Austrian vernment has a regulation to the effect that tubes, rings, ts, and the like used for feeding-bottles, and rings used bottles for preserves, which are prepared with antimony y only be employed for this purpose when they yield no timony on being treated with tartaric acid.

PANCREATITIS IN MUMPS.

THE structure of the pancreas so closely resembles that of salivary glands that the Germans have called it the bdominal parotid." This similarity suggests that the tastases of mumps should include pancreatitis. However tle has been written on the point. Perhaps the most im- rtant communication is one by M. Simonin.[1] He found at symptoms of pancreatitis occurred in ten out of 2 cases of mumps treated in the military hospital Val-de-Grâce. The pathology of the pancreatitis is ly a subject of inference, for it generally runs a nign course and no opportunity is given for examination the gland. At the meeting of the Société Médicale s Hôpitaux of Paris on July 7th Professor G. H. Lemoine d M. F. Lapasset reported a case of pancreatitis in mumps hich is of great importance, for it is the first on record in hich a necropsy has been performed. A soldier, a native of lgiers, aged 19 years, was admitted into hospital on Oct. 2nd, 02, suffering from mumps. The only previous illness as malarial fever. The case ran a benign course, the tem- erature not rising above 100·2° F. and becoming normal on e fifth day. On the eighth day the illness appeared to ave terminated but on the evening of the tenth day there as a rigor with a rise of temperature to 103 8° and pain nd swelling in the right testicle. The orchitis rapidly ubsided, the temperature became normal on the fourteenth ay, and the patient was again pronounced convalescent, ut when visited on the morning of the fifteenth day he omplained that he had not slept and that he vomited several times during the night. Although the temperature was normal he appeared to be prostrated. The conjunctivæ showed a slightly icteric tinge. The upper abdomen was tender, especially in the epigastrium and the region of the gall-bladder. Here the patient had a feeling of weight. The spleen was enlarged and tender. The pulse was slow (52) and the axillary temperature was 97·3°. An aperient was given but it was vomited and produced no action of the bowels. On the sixteenth day the icteric tint involved the whole skin and the discolouration of the conjunctivæ was more marked. Vomiting had become more frequent and the intolerance of the stomach was absolute, all liquids being rejected. The hepatic and splenic regions were very painful, with a maximum in the region of the gall-bladder, which organ appeared to be enlarged. The temperature and pulse remained the same. An injection of 1000 grammes of saline solution was ordered in order to provoke diuresis, as the kidneys had ceased to act since the previous day. In the evening the general condition seemed to have improved. Vomiting had occurred only once during the day. 80 grammes of brownish-red urine containing one gramme of albumin per litre and abundance of biliary pigments had been passed. The patient continued to be very prostrate and spoke of his approaching death. In the night the vomiting recurred and was uncontrollable. At first the vomit was black, then it gradually became sanguineous. There was also constipation. On the seventeenth day the hæmatemesis was incessant and the patient lost consciousness. The pulse rose to 120 and the temperature to 101·5° and the jaundice increased in depth. Death occurred on this day. At the necropsy all the tissues had an icteric tinge. The liver did not appear to be enlarged but it was much congested; on section it looked like a "cardiac liver." Some lobules seemed to be in a state of incipient degeneration. The gall-bladder was voluminous and œdematous. This œdema extended as far as the beginning of the common bile duct where an enlarged gland pressed on the latter and appeared mechanically to produce the œdema of the gall-bladder and the icterus. The bile in the gall-bladder was brownish, thick, and very viscid. The stomach contained black fluid; its mucous membrane was spotted with fine ecchymoses which extended as far as the first part of the duodenum. The pancreas was greatly enlarged, œdematous, and congested. It weighed 190 grammes and was of a reddish-grey colour. All the region around the pancreas, the duodenum, and the hilum of the liver contained a large number of swollen lymphatic glands. The spleen was enlarged and weighed 1200 grammes. The kidneys were a little congested and the capsules were adherent in places. Microscopic examination of the liver showed proliferation of the connective tissue surrounding the biliary canaliculi and a number of nodules composed of embryonic cells. The spleen also contained nodules of embryonic cells and its capsule and trabeculæ were thickened. In the kidneys lesions were limited to the convoluted tubes, the cells of which showed signs of granulo-fatty degeneration and the lumen of which was filled with epithelial débris. The cells and acini of the pancreas were abnormally large but the islands of Langerhans were diminished, being compressed by the turgescent tubes. The nuclei of the pancreatic cells stained badly and many of them were vesicular. The complexity of this case is noteworthy. Not only was there epigastric pain which was the principal symptom of the pancreatitis, but the gall-bladder was tender and the spleen was enlarged and tender. The symptoms of grave icterus—hæmatemesis, prostration, subnormal temperature, and elevation of temperature at the time of death—developed. The embryonic nodules found in the liver and spleen and the cellular degenerations are common to all infectious processes. Were these lesions due to the infection of mumps or were they the result of a biliary infection consecutive to the obstruction of the bile duct by the enlarged pancreatic lymphatic glands? The early appearance of the icterus in the case is in favour of the former hypothesis.

MEDICAL APPOINTMENT TO THE METROPOLITAN WATER BOARD.

Dr. Alexander Cruikshank Houston has been appointed to the important post of director of water examinations, Metropolitan Water Board, at a salary of £1000 per annum. Dr. Houston is an Edinburgh graduate and took the degrees of M.B., C.M., in 1889; B Sc. (Public Health) in 1891; and D.Sc. (Public Health) in 1892, being awarded the Gunning Victoria Jubilee Alison prize in public health and medical jurisprudence in the same year. During the past 12 years he has carried out special chemical and bacteriological researches in relation to water-supply for the Local Government Board. His investigations on the subject of lead poisoning by moorland waters (1893-97) are well known and have received favourable notice in our columns. During recent years his work for the Local Government Baord has attracted considerable attention, both in this country and abroad, and his reports on the bacteriology of soils, water, sewage, and the excrement of man and the lower animals have been widely read and appreciated. Dr. Houston has also carried out extensive researches for the London County Council on water-supply, watercress pollution, milk-supply, and disinfection; and from 1898 to 1900 he acted as bacteriologist to the main drainage committee of the Council in connexion with the purification of sewage at Barking and Crossness. During the last five years he has held the important post of bacteriologist to the Royal Commission on Sewage Disposal and has written valuable reports on the land treatment of sewage, the bacteriology of oysters and estuarial waters, and other public health subjects. Dr. Houston has frequently been called in to carry out special investigations for public bodies, his recent experiments on the sterilisation of the Lincoln water-supply being a case in point. No one has devoted more time and labour to the serious and complex problems connected with water-supply than has Dr. Houston and we have on numerous occasions pointed out the value of his work. The Metropolitan Water Board and the consumers of London water are to be congratulated on Dr. Houston's appointment to the most important "water post" that has ever been made either in this country or abroad.

---

[1] THE LANCET, Sept. 12th, 1903, p. 772.

EFFECT OF SNAKE POISON ON TRYPANOSOMATA.

Dr. Goebel of the Ghent University Institute of Hygiene and Bacteriology publishes in *La Belgique Médicale* an account of some researches on the effect of cobra poison on trypanosomata. He found that it destroyed them very rapidly at the temperature of the body but much less so at the ordinary temperature of the laboratory, while at zero (C.) it exerted practically no action at all. The effect produced was much the same as that which occurs when cobra poison is brought into contact with the red corpuscles of the blood and the dose required appears to be about the same. Dr. Goebel thinks that there is a singular analogy between the osmotic properties of trypanosomata and red corpuscles.

PERITONITIS IN TYPHOID FEVER DUE TO RUPTURE OF A CHRONIC PYOSALPINX INFECTED BY THE TYPHOID BACILLUS.

IN the *Boston Medical and Surgical Journal* of July 20th Dr. C. L. Scudder has reported a case of peritonitis in typhoid fever due to an unusual cause—rupture of a chronic pyosalpinx acutely infected by the typhoid bacillus. A married woman, aged 38 years, was admitted into hospital on May 20th. About four weeks previously she was taken ill with malaise, cramps in the abdomen, and diarrhœa. She took to bed on the 15th. Excepting the illnesses of childhood she had always been well previously. On admission the abdomen was distended, tympanitic, and somewhat rigid. The temperature was 102·2° F., the pulse was 102, the respirations were 32, and the leucocytes were 9900. On the 22nd rose spots were observed and on the following day the Widal reaction was obtained. On June 5th the temperature was nearly normal and the patient was very comfortable. At 6.30 A.M. on June 8th after a normal action of the bowels she was seized with severe pain in the abdomen, principally in the lower part. After this attack the abdomen was rigid and tender in that region. A chill followed and the temperature rose to 103·6° F. Slight moveable dulness was found in the flanks. The rigidity increased and the number of leucocytes rose from 9000 to 18,000. At noon the temperature was 105° and the pulse was 130. Vaginal examination showed in the left fornix fulness and increased resistance, with a suggestion of bogginess. Laparotomy was performed and thick puriform fluid was found throughout the abdomen. The fluid had not a fæcal odour and there was no gas in the peritoneal cavity. The appendix was normal. The ileum was examined for several feet above the cæcum but no perforation was found. On exploring the pelvis, where the pus was most abundant a left pyosalpinx was found. It corresponded to the tumou felt per vaginam. The salpingitis was chronic; the wall the sac was thick and œdematous and had rupture allowing the escape of its contents into the peritone cavity. Salpingectomy was performed. The abdomen wa flushed with saline solution and a gauze wick and drainag tubes were placed in the pelvis. Recovery followed. Th walls of the tube which was removed were covered wit exudation which on microscopic examination showed fibrous structure and round cell infiltration. The tube yielde a culture of the typhoid bacillus.

UNILATERAL PROPTOSIS AND ŒDEMA OF TH LIDS IN SCARLET FEVER.

IN the *Ophthalmoscope* for May Mr. Louis Werner ha reported a case of scarlet fever attended by an unusua complication—unilateral proptosis and œdema of the lids probably due to thrombosis of the cavernous sinus. Th patient was a boy, aged six years, who made good progre until the ninth day of an attack of scarlet fever. Then th temperature, which had been normal for two days, rose t 101·4° F. and he became drowsy. The right eye wa prominent and the lids were swollen and red. There wa no congestion of the conjunctiva. In a few days th temperature returned to normal but the ocular symptom persisted. Mr. Werner was asked to see the case. On examination there was a bright red blush over the upper li only. The lids were swollen and œdematous, especially the upper lid. The swelling was not tense or indurated and the boy could keep the eye open. No enlarged veins were visible but the lower lid was slightly bluish. Proptosis was very evident. The cornea was clear and the pupil normal in size and reaction. Unfortunately, an ophthalmoscopic examination was not then possible but a few days later, when further improvement had taken place, the fundus was found to be normal. For some weeks slight swelling of the lids occurred at variable intervals. It then disappeared but the proptosis persisted for two months. Complete recovery took place. Orbital complications are very rare in scarlet fever. A few cases of orbital cellulitis with proptosis have been observed and a case of periostitis has been recorded. Dr. Sidney P. Phillips reported three cases of unilateral œdema of the eyelids in scarlet fever complicated by otitis media. The œdema improved concurrently with the otitis media. Dr. Phillips attributed the œdema to thrombosis of the cavernous sinus and Mr. Werner adopts the same hypothesis in his case. Thrombosis might, of course, result from otitis media but primary thrombosis is also possible. Sir William R. Gowers says that primary thrombosis of the cerebral sinuses occurs most frequently in children and may follow any prostrating malady, including the specific fevers. Mr. Werner's patient was very anæmic and debilitated. The interesting points in the case are the absence of otitis media, the long duration of the proptosis after the subsidence of acute symptoms, and the complete recovery without suppuration.

THE UNIVERSITY OF MELBOURNE.

THE University of Melbourne is inviting applications for a new professorship of anatomy, with a salary of £900 per annum and £80 per annum for insurance. Professor H. B. Allen, who has hitherto held the combined chairs of anatomy and pathology, retains the professorship of pathology.

WE regret to announce the death of Dr. John William Ogle, consulting physician to St. George's Hospital, which occurred on August 8th. We hope to publish an extended notice of his career in a future issue.

BRITISH PHARMACEUTICAL CONFERENCE.

THE forty-second annual meeting of the British Pharmaceutical Conference was held at the Hôtel Métropole, Brighton, from July 24th to 28th. This conference is solely concerned with the encouragement of pharmaceutical research and the promotion of friendly intercourse and union amongst pharmacists. It thus differs from the armaceutical Society of Great Britain which is a statutory dy charged with the administration of the Pharmacy Acts d the examination and registration of those who desire to registered under these Acts. The members of the conferce were received by the Mayor of Brighton at the Royal avilion on July 24th and on the following morning the Presient, Mr. W. A. H. Naylor, F.I.C., of London, delivered address[1] on the Standardisation and Storage of Drugs fter which the reading and the discussion of communiations arising from researches were commenced. The conerence was attended by nearly 300 pharmacists and many adies from all parts of the United Kingdom, together with everal colonial pharmacists. Excellent arrangements had een made by the pharmacists of Brighton and Eastbourne to ender the meeting a social success, the round of amuseents including dances, smoking concerts, drives, a trip by ea to Eastbourne, and a whole day excursion to Arundel, he magnificent Sussex seat of the Duke of Norfolk.

Of the 20 papers read before the conference the majority were of purely pharmaceutical interest. The remainder possessed some medical interest, particularly a paper by Professor W. E. DIXON on

The Physiological Standardisation of Drugs, including a Suggested Physiological Standard for Insertion in the next British Pharmacopœia.

Professor Dixon dealt with certain drugs—e.g., ergot, cannabis indica, lobelia, grindelia, hemlock, and the digitalis group, including digitalis, strophanthus, and squill—for all of which there was at present no trustworthy chemical method of analysis. For such drugs the biochemical method of determining the strength was applicable and should be resorted to in order to obtain galenical preparations having a fixity of strength. The drugs which especially required standardising were the members of the digitalis group, ergot, and cannabis indica. It was necessary to apply biochemical tests to the lower animals owing to the difficulty of recognising small effects in man and the danger of the experiments involved. The principal difference in the action of drugs on man and animals occurred with those remedies which attacked the central nervous system. This point was made clear in a table which showed the degree of development of the brain in different animals and the amount of cocaine required to produce convulsions:—

Animal.	Grammes of brain per kilogramme of animal.	Dose in grammes of cocaine per kilogramme of animal required to produce convulsions.
Rabbit	4	0·18
Guinea-pig	7	0·07
Pigeon	8	0·06
Dog	9	0·02
Ape	18	0·012

But on other tissues the difference was not apparent. If a drug attacked the heart of a man in a certain way it attacked the heart of every mammal in precisely the same way; or if the attack was upon glands the type of action was constant in all mammalia. To take one example of this, secretin was a remedy prepared from the duodenum; it increased the flow of pancreatic juice as was the case with no other drug. But secretin prepared from man or dog had precisely the same effect on the pancreas of every vertebrate throughout the animal kingdom, including that of the frog. The principal objection to this type of experiment was that the reagent—namely, the animal—was too sensitive, so that changes in the conditions under which the experiments were performed might lead to some error. However, if due precautions were taken to keep the conditions of experiment as constant as possible this method of standardisation was wonderfully accurate. The members of the digitalis group might be standardised on male frogs, weighing about 25 grammes each. A tincture of the drug to be standardised was diluted with an equal volume of water and injected into the dorsal lymph sac. Six minims of the diluted tincture should kill the frog by stoppage of the heart within an hour. Professor Dixon proposed that three minims should form the standard unit and that all tinctures of digitalis should bear a label stating how many minims went to the unit. Supposing it was found that five minims of a diluted tincture was the maximum lethal dose then this tincture should be diluted with water to bring it down to the standard. If, however, eight minims of a diluted tincture formed the maximum lethal dose then the label should state that the unit corresponded to four minims instead of three minims. This did not necessarily mean that a prescription containing digitalis should differ in any way from a present-day prescription, but the quantities prescribed by the physician would refer to standardised tincture. If the chemist's tincture was not of standard strength he could by a simple proportion sum calculate the necessary quantity of his tincture to correspond to the quantity prescribed. Tincture of strophanthus was invariably more toxic than that of digitalis. In treatises on medicine it was stated that in certain cases of cardiac disease where digitalis failed to give relief strophanthus might succeed. The explanation was that strophanthus preparations were more powerful than those of digitalis and were absorbed more quickly into the system. But as tincture of strophanthus had the same dose as that of digitalis it should have an equal toxicity. It might be standardised in precisely the same way as digitalis. This would generally require the dilution of the tincture as at present prepared to bring it down to the same standard. Tincture of squill might be standardised in the same way. It was usually a little less toxic than digitalis. This method of assaying could be controlled still more accurately upon rabbits and it was generally advisable that such control experiments should be performed. Professor Dixon deferred the publication of the details of these experiments till later, as well as the methods of standardising the other preparations of this group. Ergot was another drug that varied enormously in its activity. Professor Dixon recently obtained six specimens of the liquid extract from six different sources. Two of these were moderately active, two possessed a feeble action, and the remaining two either had no action at all or their effect was so feeble as to be absolutely worthless for therapeutic use. At the present time the only method of standardising ergot that had been adopted was the injection of the drug into roosters. If the dose was sufficiently large they developed gangrene on the comb and wattles after the necessary interval of time. This method was open to several objections, of which the most important, perhaps, was the difficulty of determining the miminal dose that would produce gangrene. In the opinion of Professor Dixon it was doubtful whether the production of gangrene was in any way proportional to, or indicative of, the therapeutic action required when ergot was administered. The gangrene was not due to simple constriction of the vessels but to a secondary degeneration of the vessels which resulted in the complete blocking of the arterioles. Professor Dixon found, however, that the rise in blood pressure in mammals was proportional to the effect of ergot upon the uterus. This rise was mainly due to constriction of the vessels. Hence, by measuring the increase of blood pressure under fixed conditions they possessed a method of standardisation which was rapid, trustworthy, and proportional both to the vaso-constriction and the effect on the uterus, which were the two principal uses of ergot in therapeutics. The experiments should be performed on rabbits, conforming as nearly as possible to a standard weight and anæsthetised with urethane, of which 1·25 grammes per kilogramme body-weight were necessary to complete anæsthesia. In this way all the disturbing influences of a volatile anæsthetic were avoided. The blood pressure might be taken from the carotid artery and the liquid extract of ergot injected into the femoral vein. The injection should occupy a definite fixed time and the fluid should be at the temperature of the body. Experiments performed in this way afforded a sure method of determining to a fine degree of accuracy the relative activity of different specimens of ergot. Professor

---

[1] Vide THE LANCET, July 29th, 1905, p. 304.

Dixon deferred to a future communication suggestions as to the exact amount of ergot necessary to produce the standard rise in blood pressure. Cannabis indica was another drug which varied greatly in toxicity, owing to the varying climatic conditions in which the plant was grown. It could not be assayed on animals with the same degree of accuracy as the drugs previously mentioned because the action was on the central nervous system and because the degree of action must be gauged by the experimenter and could not be recorded. The tincture should be diluted with an equal volume of water and ten minims injected subcutaneously into a cat about two and a half kilogrammes in weight. In an ordinarily active sample this animal soon began to show physical signs of intoxication. The pupils dilated, the reflexes were increased, and the gait became exceedingly awkward, the animal rolling from side to side and showing other signs of incoördination. Quite a number of tinctures on the market, even in four times this dosage, produced no effect at all, whilst a few others produced a greater degree of intoxication. Lobelia could be standardised very accurately by its effect upon blood pressure and its subsequent paralytic action on certain nerve cells. Professor Dixon had often found lobeline, like many of the so-called active principles derived from digitalis, to be quite inactive. In the case of opium it might occasionally be necessary to test for the presence of excessive amounts of alkaloids other than morphine. It was well known that some specimens of opium produced excitement and increased reflexes due to the presence of excessive quantities of narcotine. In such cases the injection of the opium into a frog led very quickly to convulsions and afforded a test of the usefulness of the opium. In conclusion Professor Dixon pointed out that pharmacological methods of standardisation should only be resorted to when chemical methods were inadequate. In the examples given it was the only method available.

A paper was read by Mr. STANLEY READ, L.D.S. R.C.S. Eng., on

The Composition of Dentifrices as affected by Recent Investigation in Dental Science.

Mr. Read in his paper put forward the view, based on the researches of Dr. Miller of Berlin, that the use of antiseptic substances in dentifrices was wrong in principle as they were likely to destroy the protective bacteria which were normally present in the mouth as well as those which produced dental caries. On this view a dentifrice was regarded merely as a mechanical agent for removing stains.

Mr. D. B. DOTT, F.I.C., contributed a paper on

Mercurio Zinc Cyanide.

Mr. Dott drew attention to the variableness of this substance and gave reasons for believing that it was not a definite compound. He suggested the adoption of an arbitrary standard of strength, say 20 per cent. of mercuric cyanide.

Mr. W. HARRISON MARTINDALE, Ph.D. Marburg, gave an interesting summary of

Recent Work on Radio-activity.

This paper included an account of experiments which had been made on the internal use of radium for therapeutic purposes. Other radio-active salts, notably those of uranium and thorium, which had the advantage of comparative cheapness, were dealt with by Dr. Martindale.

A valuable paper was contributed by Mr. A. W. GERRARD, dealing with

Capsicum and its Preparations.

This paper was mainly of pharmaceutical interest but one important fact may be referred to—viz., that alcohol was the best solvent of the active constituents of capsicum.

Another interesting paper read at the conference was a preliminary communication from Mr. H. FINNEMORE, A.I.C., and Mr. H. DEANE, B.Sc., A.I.C., entitled

Castor Oil (Part I.).

This paper consisted of a summary of work that had been done on castor oil by previous investigators. From this it appeared that the therapeutic activity of the oil was due to the fatty acids.

Mr. H. WIPPELL GADD, F.C.S., read a preliminary paper on

The Chemistry and Pharmacy of the Leaves of Viola Odorata.

From the experiments described in the paper Mr. Gadd concluded that any therapeutic activity which violet leaves might possess was due either to a glucoside or to the products of its decomposition or to a natural ferment associated with it. About three and a quarter ounces of the leaves were infused in a pint of boiling water and the infusion taken internally or applied externally as a fomentation. The leaves which were most sought after at the present time were those of a cultivated variety of the *odorata* group and known to horticulturists as the "Princess of Wales." He found that this variety had a stronger taste than the wild violets possess.

In a discussion which followed the reading of this paper Mr. G. CLARIDGE DRUCE, M.A. Oxon., curator of the botanic gardens at Oxford, pointed out that the reputation of violets for the treatment of malignant growths was founded on the use of wild violets at least as far back as the days of James I. It was desirable, therefore, that in any inquiry into the subject wild violets should be used, such as had been used for centuries, and not a recent cultivated variety as was employed at the present time.

MEDICINE AND THE LAW.

The Cheap Pistol Again.

SINCE the passing of the Pistols Act, 1903, accidents of a dangerous or fatal character resulting from boys playing with revolvers bought in toy shops have no doubt been less frequent than formerly and crimes perpetrated with weapons which anyone could buy without restriction for a few shillings may have diminished in number. At the same time neither of these two classes of avoidable death and injury can be said to have disappeared and in instances where shopkeepers have been prosecuted for not complying with the terms of the Act their usual excuse has been ignorance of the law, which may not be a legal defence but which usually serves to mitigate the penalty imposed. At Bow-street recently, for example, a shopkeeper in the Euston-road pleaded ignorance of the law when summoned for selling a revolver to a boy under the age of 18 years. This youth, who was aged 14½ years, had been told that he must have a licence and had gone to the nearest post-office where he obtained one without difficulty, which points to an omission in safeguarding the public. Many lads under 18 years of age shoot but there can be no reason why their licences should be supplied directly to them instead of on the authority and responsibility of a parent or guardian. The lad then proceeded to write to the Commissioner of Police and to ask that authority whether he would be justified in shooting anyone who insulted him. His letter, which might suggest somewhat unusual mental conditions, had the effect of provoking inquiry and the prosecution was instituted, with the result that the vendor of the pistol was fined 40*s.* with costs. Apparently he was aware of the need for a licence on the part of the customer but did not know of the age limit. Surely, however, there is no reason why it should not be impossible for any tradesman even to suggest ignorance of a law which particularly affects himself. Every shopkeeper's door must be passed by a policeman from time to time and a warning given by the police would readily afford information as to an Act of this kind within a day or two of its being passed, while the statute itself only occupies a couple of printed pages and a copy of it costs 1*d.* or 1½*d.* Moreover, it provides for the keeping of a book in which the sale of pistols is to be recorded and this is open to inspection by any officer of the police or of the inland revenue. The Act must necessarily be useless if no effort is made to enforce it until a breach of it is brought to the notice of the authorities.

Common Lodging-houses further Defined.

The appeal in the case of Gilbert *v.* Jones, heard by the Lord Chief Justice, Mr. Justice Lawrance, and Mr. Justice Ridley in the Divisional Court on August 2nd, will strengthen the hands of local authorities in dealing with certain charitable institutions which at any time might have become otherwise a source of danger to the health of the community. The decision will affect one or two other prosecutions which have been adjourned in order to await it, the facts being that Father Gilbert, a benevolent Roman Catholic clergyman, had opened a night refuge for the most destitute classes of the community without obtaining a licence as for a common lodging-house. There was no suggestion that the house was not admirably conducted from a sanitary point of view but the London County Council maintained nstitutions of this class must under the law be d as common lodging-houses and as such subject to ion, it being obvious that if improperly kept from a y point of view the circumstance that no payment ken from the inmates would make no difference to obability of the spread of disease. The only point by the appellant, who had been convicted by Cluer of the offence alleged, consisted in the e of all payment. It was held once upon a in the case of Salvation Army shelters, where a sum was charged but where no profit was made by my, that these were not common lodging-houses; this, er, had been overruled long before Mr. Gilbert led by a court over which Lord Russell of Killowen led. The court therefore had to decide whether there ny distinction to be made between a night refuge or ng house where the lodgers paid a trifle, as in the case he Salvation Army refuges, and one in which there no charge made of any kind, and in which, as quite fairly argued, the lodgers might be looked as the guests of those maintaining the institu- Lord Alverstone delivered the judgment of the t upholding the conviction. He was unable to draw the nction which he was invited to, between the charitable e where a small payment was exacted and that in which e was none at all, and he pointed out that the decision lved no interference whatever with any charitable work ied out under proper sanitary conditions. In dismissing appeal he granted an application for costs on behalf of London County Council who, as Mr. Avory, K.C., it, were, in fact, the ratepayers of London and none uld question the justice of this. It is unreasonable of ritable persons dealing with difficult social and sanitary blems to maintain that because their own work is ond reproach they, and with them others who may less scrupulous, should be beyond the reach of all ticism. Certainly they have no right to expect to have ir errors of judgment paid for by the ratepayers.

Accident or Disease?

The Workmen's Compensation Acts, as lawyers have good son gratefully to remember, while providing for the pay- nt of compensation to workmen incapacitated by "acci- nt" omitted to define the manner in which this word was be interpreted. Such mishaps as rupture when lifting avy weights and infection with anthrax have been declared various times to be "accidents," and the tendency has doubt been to extend the meaning of the word beyond e sense in which it is used in everyday life. At loomsbury county court recently a man claimed as for an ccident compensation for his loss of employment when ffected by caisson disease, the defendants being the contractors for the new tube railway from Charing Cross to ampstead. Judge Bacon, after hearing argument and the uthorities upon the subject, refused to hold that caisson isease was an accident but presumably the Court of Appeal nd possibly the House of Lords will be asked to review his ecision. It would be interesting to ascertain the legal xpenses that might have been saved by a fuller definition in he original Bill upon this point alone. The question is of some interest to medical men who are the most important witnesses in compensation cases of this kind and who naturally find it useful to know when treating a case whether they will some day have to depose to symptoms and treatment in a court of law.

LITERARY INTELLIGENCE.—A work on Criminal Responsibility will shortly be issued from the Oxford University Press. The author is Dr. Charles A. Mercier and the book is intended to complement that by Sir FitzJames Stephen. Dr. Mercier points out that the question of criminal responsibility should be considered anew by a psychologist—Sir FitzJames Stephen was handicapped by insufficient knowledge of the work of the mind in health and disease—and that in 20 years our knowledge of insanity has advanced.—A book is to be published in the autumn by the De La More Press entitled "A First German Course for Science Students," and written by Professor H. G. Fiedler and Dr. F. E. Sandbach. The book assumes no previous knowledge of German and consists of German passages, the vocabulary of which is strictly scientific. It is printed in the English characters and illustrated and contains a brief outline of grammar and a vocabulary.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On the General Sanitary Circumstances and Administration with Special Reference to Infectious Diseases of the County Borough of Hanley, by DR. S. MONCKTON COPEMAN.[1]—The borough of Hanley (population 63,889) in the Staffordshire pottery district presents several interesting problems in public health administration. On the question of housing Dr. Copeman shows that although there is sufficient accommodation for the working classes who are able and willing to pay for it, much difficulty arises with regard to a considerable proportion of the poorest class, largely Irish, who apparently cannot afford to pay a higher rent than 2*s.* 6*d.* a week. People of the latter class inhabit a set of areas which are extremely insanitary in their condition but with which it is evidently not easy to deal under the Housing of the Working Classes Acts. Proposals for municipal dwellings for the very poor have been made but it would probably be found impossible to supply such dwellings without entailing a considerable burden on the local rates. Another special difficulty in Hanley results from the frequent subsidences of the surface of the ground on which the town is built, due to sinking of old mine workings. In some instances water mains have been broken from this cause and bacteriological evidence has been obtained that objectionable pollution of the water supplied to certain areas of the borough has resulted from the fractures. For similar reasons sewers often need renovation or repair. In the course of five years it has been necessary to open up sewers for repairs of one or another kind as often as 704 times and on several occasions the sewers in question have had to be relaid wholly or to be abandoned in consequence of the extent of the settlement. Gas mains are also frequently affected by these subsidences. The steepness of gradients in certain of the sewers has rendered them liable to damage from excessive pressure in time of rain. A complete "separate system," dealing with storm water by separate sewers, is now contemplated. Large new works of sewage-disposal by means of tanks and continuous filters are being constructed. House drainage is often defective, the pipes until a few years ago having been jointed merely with clay. Another serious defect in the borough consists in the accumulations of house refuse which are allowed to take place in the numerous large middens. Where moveable ashbins have been provided their contents are emptied not more often than once a week. Frequently in the process of emptying receptacles for house refuse it is necessary to carry the refuse through the living rooms of the house, while it is a common practice to dump the collected material in heaps either in the street or alongside the footpaths to await the arrival of the scavenger's cart. "This method," Dr. Copeman observes, "would be sufficiently objectionable were the process carried on early in the morning. But it not unfrequently happens, as I was informed, that the cart may make its rounds in the busiest hours of the day or at a time when children are playing about in the streets between school hours." Various methods of disposal of excrement exist—Rochdale pails, Duckett's and Fowler's slop-water closets, cesspit privies, and water-closets with or without flushing cisterns. The supply of water to closets which possess flushing-apparatus is often cut off by the water company for non-payment of rates and in consequence a great many flushing cisterns have fallen into disuse. Dr. Copeman draws attention to the advantage of the Hanley public abattoir and considers that it would be a most desirable reform to enlarge it and to abolish the private slaughter-houses which still exist in the borough. For some years the general death-rate in Hanley has remained at a higher figure than the average for the 76 greater towns included in the Registrar-General's weekly returns and the same has been true for the infantile mortality. To a large extent this higher death-rate has been due to continued and excessive prevalence of infectious diseases—diphtheria, enteric fever, measles, and summer diarrhœa—during recent years. The heavy infantile mortality, in the opinion of Mr. J. Clare, the borough medical officer of health, is attributable to the excessive employment of adult female labour in the Potteries, which leads to bad feeding by hand and to many children being put out to nurse. Dr. Copeman points out the various ways in which the pollution of soil in the neighbourhood of the dwellings probably conduces to the propagation of the infection of summer diarrhœa and of enteric fever. Between 200 and 500 cases of diphtheria have been reported annually since 1899 and the average case mortality from this disease during the past six years is no less than 20 per cent. Dr. Copeman discusses the share of schools in spreading infection and draws attention to the manner in which epidemic diphtheria in recent years has slowly spread from one to another of the adjoining townships in the Potteries. In making recommendations attention is drawn to the need for revision of by-laws and the report states that the long delay in dealing with this matter has been largely due to overwork of the borough surveyor who in addition to his numerous other duties has been acting as engineer to the new electrical installation of the borough. Municipal enterprise in such matters as electric light may be well enough but obviously it should not be so indulged in as to encourage neglect of important measures of public health. Hanley has the population and the dignity of a county borough and Dr. Copeman strongly recommends that the town council should follow the example of the majority of such boroughs and pay a salary to its medical officer of health which will enable him to devote the greater part of his time to official duties. This step would obviously place the sanitary service of the town in a much better position for effective work than it at present occupies.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8719 births and 5080 deaths were registered during the week ending August 5th. The annual rate of mortality, which had been 12·9, 13·4, and 15 0 per 1000 in the three preceding weeks, further rose last week to 17·0 per 1000. In London the death-rate was 15·6 per 1000, while it averaged 17·6 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 6·0 in King's Norton, 7·4 in Hornsey and in Reading, 7·6 in Handsworth (Staffs), 7·9 in Bournemouth, 9·0 in Walthamstow, in Northampton, and in Great Yarmouth, 9·2 in Croydon, and 9·6 in Leyton; the highest rates were 22·8 in West Ham, 22·9 in Warrington, 23·2 in St. Helens, 23·5 in Wigan, 23·7 in Grimsby, 24·1 in Bootle, 24·3 in Tynemouth, 24·4 in Stockport, 26·9 in West Bromwich, 28·4 in Sheffield, and 62·2 in Rhondda.[1] The 5080 deaths in these towns last week included 1507 which were referred to the principal infectious diseases, against 486, 612, and 1101 in the three preceding weeks; of these 1507 deaths, 1247 resulted from diarrhœa, 77 from whooping-cough, 71 from measles, 44 from diphtheria, 39 from scarlet fever, 28 from "fever," and one from small-pox. No death from any of these diseases was registered last week in Burton-on-Trent, and while Croydon, Hornsey, Hastings, Brighton, Bournemouth, King's Norton, Bury, Swansea had low death-rates from the principal infectious diseases, the highest rates were recorded in West Ham, Grimsby, Birkenhead, Liverpool, Bootle, Wigan, Sheffield, and Rhondda. The greatest proportional mortality from measles occurred in Barrow-in-Furness, ; from scarlet fever in Blackburn; from whooping-cough in West Ham, Oldham, and Rhondda; and from diarrhœa in West Ham, Grimsby, Birkenhead, Liverpool, Bootle, Wigan, Sheffield, and Rhondda. The mortality from diphtheria and from "fever" showed no marked excess in any of the large towns. One fatal case of small-pox was registered in Birmingham but none in any other of the 76 towns. The number of small-pox cases remaining under treatment in the Metropolitan Asylums Hospitals, which had been four, three, and three at the end of the three preceding weeks, was two at the end of last week; three new cases were admitted during the week, against two, none, and none in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday last, August 5th, was 2632, against 2520, 2485, and 2550 on the three preceding Saturdays; 366 new cases were admitted during the week, against 356, 304, and 352 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 104, 117, and 116 in the three preceding weeks, fell to 111 last week, and were one below the number in the corresponding period of last year. The causes of 46, or 0·9 per cent., of the deaths in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Portsmouth, Bristol, Salford, Leeds, and in 47 other smaller towns; while the largest proportions of uncertified deaths were registered in Birmingham, Leicester, Liverpool, Manchester, Sheffield, Gateshead, and Newcastle-on-Tyne.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 14·3, 15·2, and 15·3 per 1000 in the three preceding weeks, fell to 14·8 per 1000 during the week ending August 5th, and was 2·2 per 1000 below the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 8·7 in Aberdeen and 10·2 in Leith to 16·8 in Perth and 18·3 in Paisley. The 496 deaths in these towns last week included 59 which were referred to diarrhœa, 15 to measles, 14 to whooping-cough, two each to scarlet fever, diphtheria, and "fever," but none to small-pox. In all 94 deaths resulted from these principal infectious diseases last week, against 55, 61, and 66 in the three preceding weeks. These 94 deaths were equal to an annual rate of 2·8 per 1000, which was 2·2 per 1000 below the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of diarrhœa, which had been 7·22 and 39, further rose last week to 59, of which 36 occurred in Glasgow, nine in Edinburgh, and four in Leith. The deaths from whooping-cough, which had been 25, 12, and 14 in the three preceding weeks, were again 14 last week, and included five in Edinburgh, four in Glasgow, and two in Dundee. The fatal cases of measles, which had been 19, 21, and eight in the three preceding weeks, rose to 15 last week, of which ten were registered in Glasgow and two in Edinburgh. The deaths from diphtheria, which had been one, three, and five in the three preceding weeks, declined to two last week, both deaths having occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 65, 62, and 70 in the three preceding weeks, fell last week to 48, and were one in excess of the number in the corresponding period of last year. The causes of 13, or 2·6 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 19·7, 20·1, and 20·8 per 1000 in the three preceding weeks, further rose to 21·2 per 1000 during the week ending August 5th. During the past four weeks the death-rate has averaged 20·5 per 1000, the rates during the same period being 13·6 in London and 15·9 in Edinburgh. The 154 deaths of persons belonging to Dublin registered during the week under notice were three in excess of the number in the preceding week and included 29 which were referred to the principal infectious diseases, against 17, 20, and 22 in the three preceding weeks; of these, 25 resulted from diarrhœa, two from diphtheria, and two from whooping-cough, but not any from small-pox, measles, scarlet fever, or "fever." These 29 deaths were equal to an annual rate of 4·0 per 1000, the mean rates last week from the principal infectious diseases being 4·2 in London and 2·8 in Edinburgh. The fatal cases of diarrhœa, which had been 14, 18, and 20 in the three preceding weeks, further rose last week to 25. The 154 deaths in Dublin last week included 52 of children under one year of age and 29 of persons aged 60 years and upwards; the deaths of infants exceeded the number in the preceding week by one, and those of elderly persons showed an increase of six deaths. Two inquest cases and three deaths from violence were registered; and 53, or more than a third, of the deaths occurred in public institutions. The causes of seven, or 4·5 per cent., of the deaths registered in Dublin last week were not certified.

---

[1] Excluding 79 deaths due to the colliery explosion at Wattstown, the death-rate in Rhondda during the week would have been 29·2.

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON.

(*Specially compiled for* THE LANCET.)

Cities and Boroughs.	Estimated population in the middle of 1905.	Notified Cases of Infectious Disease.											Deaths from Principal Infectious Diseases.											Deaths from all causes.	Death-rate per 1000 living.	Deaths of infants under one year to 1000 births.
		Small-pox.	Scarlet fever.	Diphtheria.*	Typhus fever.	Enteric fever.	Other continued fevers.	Puerperal fever.	Erysipelas.	Cholera.	Total.	Annual rate per 1000 persons living.	Small-pox.	Measles.	Scarlet fever.	Diphtheria.*	Whooping-cough.	Typhus fever.	Enteric fever.	Other continued fevers.	Diarrhœa.	Total.	Annual rate per 1000 persons living.

VITAL STATISTICS OF LONDON DURING JULY, 1905.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious disease it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 6·8 per 1000 of the population, estimated at 4,684,794 persons in the middle of the year. In the three preceding months the rates had been 5·6, 6·2, and 6·8 per 1000 respectively. The lowest rates last month were recorded in Kensington, the City of Westminster, St. Pancras, Holborn, the City of London, and Greenwich; while the highest rates occurred in Fulham, Shoreditch, Bethnal Green, Stepney, and Poplar. Small-pox was less prevalent than it had been in the preceding month; of the four cases notified during July one each belonged to Islington, Finsbury, Bethnal Green, and Deptford. The Metropolitan Asylums hospitals contained three small-pox patients at the end of last month, against 16, nine, and four at the end of the three preceding months; the weekly admissions averaged one, against four, two, and two in the three preceding months. The prevalence of scarlet fever was slightly greater than in the preceding month; among the various metropolitan boroughs this disease was proportionally most prevalent in Fulham, Shoreditch, Bethnal Green, Stepney, Poplar, Camberwell, and Deptford. The number of scarlet fever patients in the Metropolitan Asylums hospitals, which had been 2152, 2236, and 2444 at the end of the three preceding months, had further risen to 2527 at the end of last month; the weekly admissions averaged 338, against 266, 302, and 301 in the three preceding months. Diphtheria was slightly less prevalent during July than in the preceding month; the greatest proportional prevalence of this disease occurred in Stoke Newington, Hackney, Stepney, Poplar, and Woolwich. The Metropolitan Asylums hospitals contained 785 diphtheria patients at the end of July, against 719, 684, and 715 at the end of the three preceding months; the weekly admissions averaged 118, against 83, 89, and 111 in the three preceding months. The prevalence of enteric fever was considerably greater than in the preceding month; among the various metropolitan boroughs this disease was proportionally most prevalent in Paddington, Chelsea, St. Marylebone, Hackney, Shoreditch, Bethnal Green, and Stepney. The number of enteric fever patients remaining under treatment in the Metropolitan Asylums hospitals at the end of last month was 94, against 65, 80, and 78 at the end of the three preceding months; the weekly admissions averaged 17, against 11, 14, and 10 in the three preceding months. Erysipelas was proportionally most prevalent in Paddington, Chelsea, St. Marylebone, Hackney, Shoreditch, Bethnal Green, and Stepney. The 16 cases of puerperal fever notified during the month included two in the City of Westminster, two in Stepney, and two in Southwark.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various boroughs, the deaths occurring in public institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the four weeks ending July 29th the deaths of 4279 persons belonging to London were registered, equal to an annual rate of 11·9 per 1000; in the three preceding months the rates had been 15·1, 14·0, and 12·1 per 1000. The rates last month ranged from 6·9 in Lewisham, 8·3 in Hampstead, 9·6 in Islington, 9·8 in Camberwell, and 9·9 in Wandsworth, to 14·0 in the City of London and in Stepney, 14·4 in Bethnal Green, 14·6 in Fulham and in Poplar, 17·4 in Finsbury, and 22·9 in Shoreditch. The 4279 deaths from all causes in London last month included 604 which were referred to the principal infectious diseases; of these, 91 resulted from measles, 32 from scarlet fever, 24 from diphtheria, 78 from whooping-cough, 17 from enteric fever, one from ill-defined pyrexia, and 361 from diarrhœa, but not any from small-pox or from typhus fever. No death from any of these diseases was recorded in Stoke Newington; among the metropolitan boroughs they caused the lowest death-rates in Chelsea, the City of Westminster, Hampstead, the City of London, Camberwell, and Lewisham; and the highest rates in Fulham, Finsbury, Shoreditch, Bethnal Green, Stepney, and Poplar. The 91 deaths from measles were but half of the correct average number; among the various metropolitan boroughs this disease was proportionally most fatal in Paddington, the City of Westminster, Finsbury, Shoreditch, and Wandsworth. The 32 cases of scarlet fever were 14 below the average for the corresponding periods of the ten years; the greatest proportional mortality from this disease occurred in Fulham, Bethnal Green, Poplar, Lambeth, and Battersea. The 24 deaths from diphtheria showed a decline of 97 from the corrected average number; among the various metropolitan boroughs this disease was proportionally most fatal in Kensington, Fulham, Hackney, Bethnal Green, and Poplar. The 78 deaths from whooping-cough were 53 below the average number in the corresponding periods of the ten preceding years; this disease showed the greatest proportional mortality in Fulham, Islington, Finsbury, Shoreditch, Stepney, Poplar, Lambeth, and Battersea. The 18 fatal cases of "fever" showed a decline of 15 from the corrected average number; four of the deaths belonged to Stepney, three to Islington, and two to St. Marylebone. The 361 deaths from diarrhœa were 291 below the average number in the corresponding periods of the ten preceding years; this disease was proportionally most fatal in Fulham, Hackney, Finsbury, Shoreditch, Bethnal Green, Stepney, and Poplar. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases was more than 45 per cent. below the average.

Infant mortality, measured by the proportion of deaths among children under one year of age to registered births, was equal to 112 per 1000. The lowest rates of infant mortality were recorded in St. Marylebone, Holborn, the City of London, Camberwell, Lewisham, and Woolwich; and the highest rates in Kensington, Fulham, Hackney, Finsbury, Shoreditch, and Bethnal Green.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeon E. H. H. de Courtmacsherry, to Royal Naval Engineering College, Keyham. Surgeons: H. F. Iliewicz to the *Powerful*; J. Barry to the *Centurion*; G. E. Kennedy to the *Royal Oak*; A. J. Pickthorn to the *Ocean*; and W. P. Dyer and C. R. Sheward to the *President*, for three months' study at West London Hospital.

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 3rd Kent (Royal Arsenal): Bernard Hudson to be Surgeon-Lieutenant (dated July 8th, 1905).

Rifle: 1st Volunteer Battalion the Suffolk Regiment: Herbert Mayris Sylvester to be Surgeon-Lieutenant (dated August 1st, 1905). 3rd Volunteer Battalion the Bedfordshire Regiment: Surgeon-Captain J. W. Bone resigns his commission (dated August 1st, 1905). 3rd Volunteer Battalion the East Surrey Regiment: Richard William Brimacombe to be Surgeon-Lieutenant (dated August 1st, 1905). 1st Volunteer Battalion the Gordon Highlanders: Surgeon-Major G. M. Edmond resigns his commission (dated August 1st, 1905). The Prince of Wales's Own 12th Middlesex (Civil Service): Acting Surgeon Robert Welsh Branthwaite, Cadet Corps (Civil Service), attached to the Prince of Wales's Own 12th Middlesex (Civil Service) Volunteer Rifle Corps, to be Surgeon-Lieutenant and to be borne as Supernumerary to the Establishment (dated July 31st, 1905). 14th Middlesex (Inns of Court): The undermentioned officer resigns his commission:—Surgeon-Captain F. C. Wallis (dated July 17th, 1905).

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Major A. B Wade to be Surgeon-Lieutenant-Colonel (dated July 29th, 1905) Surgeon-Lieutenant-Colonel D. E. Flinn, having resigned his commission in the Volunteers, ceases to belong to the Army Medical Reserve of Officers (dated August 5th, 1905).

OUR ARMY MEDICAL SERVICE.

The following is an extract from Lord Roberts's address on Imperial defence on August 1st at a special meeting of members of the London Chamber of Commerce at the Mansion House, as reported in the *Times*, August 2nd, 1905:

> Alarming as the figures I have quoted are, they only apply to the combatant branch of the army; there are other important branches upon the efficiency of which the success of a campaign in no small degree depends. One very important branch is the medical. There

is a great outcry in this country during the South African war when became known that the number of medical officers and nurses was sufficient and that there was a lack of proper hospital equipment id appliances. Civil surgeons and nurses were hurriedly entrained, dditional field hospitals were despatched, and the timely aid afforded by rivate persons was eagerly accepted. But the fact remains that for the rst few months of the war the medical arrangements were quite unequal o cope with the strain put upon them. For this I do not think anyone an be blamed. Certainly not the medical officers, who were most evoted and untiring in their endeavours to overcome the enormous ifficulties with which they had to contend. It had been generally ccepted that the *maximum* strength of any force despatched from this ountry would not exceed two army corps—say, 75,000 men—whereas the rce actually employed amounted to between 300,000 and 400,000 scattered ver a vast area with inadequate rail transport, and for the greater part ithout roads. But it will not be possible on any future occasion to ake allowances for failure in the medical arrangements. We have een taught by sad experience that we must be prepared for a much rger force being sent into the field than was contemplated before the outh African war and a much larger percentage of disease. Yet at resent we are not much better off as regards medical requirements han we were in 1899; for although the Royal Army Medical Corps was ncreased by 125 officers and 1200 other ranks under Mr. Brodrick's *égime*, out of its own establishment it can now only provide for an xpeditionary force 55,000 strong. It has been proposed to supplement the *personnel* by the addition of 45 per cent. of civil surgeons and 7 per cent. of civil subordinates, which would provide for a force 3,000 strong; and certain further proposals have been made by the dvisory Board which if adopted would enable the Royal Army Medical orps to deal with a force 140,000 strong. But both these proposals are till only under consideration, nothing has been done, and, as matters ow stand, the balance of any larger force than 55,000 would have to ake the field without any properly trained establishment whatever. No help could possibly be afforded to the army in India, which would e sadly in need of medical aid in the event of a prolonged war.

"Audi alteram partem."

MISTAKES IN THE DIAGNOSIS OF INFECTIOUS DISEASE.

To the Editors of THE LANCET.

SIRS,—The statement of the chairman of the statistical committee of the Metropolitan Asylums Board last week and the pointed prominence given to it by the press (with respect to the 2000 mistakes and loss of £12,000 of the ratepayers' money), on the face of it implies, and is no doubt intended so to do, a grave reflection on the competency of the London medical men and draws marked attention to their inability to diagnose correctly the various infectious disorders to which they may in their daily round be called and the consequences thereof to the public. I am willing to acknowledge that it is unfortunate so many should have occurred and that not only has the money been to all intents and purposes wasted but also that the patients have been needlessly brought into contact with diseases which they themselves did not suffer from—a much more serious matter than loss of money and time; but is there nothing to be said on behalf of the poor practitioner who is called on suddenly to make an immediate diagnosis of the case and to act on it? As one of these latter, and one whose diagnosis having been reviewed has been found wanting, may I be allowed to plead extenuating circumstances in mitigation of judgment and explain *some* of the possible circumstances in which some of these errors occur?

The case to which I was called was apparently one of diphtheria and I gather from the general statement in the newspapers that many or most of the errors occurred in diagnosing this disorder. I say apparently it was one of diphtheria, for all the clinical symptoms were identical with those of that disorder. It occurred in the house of a training home for servant girls, with no possible accommodation for isolation. What was one to do? Theoretically one ought to have isolated the patient until one had taken a swab from the throat and had this examined and the diagnosis confirmed or otherwise. In the circumstances, however, I took on myself the responsibility of notifying the case and of having it immediately removed, and with all that I now know (and I have had a very considerable acquaintance with diphtheria) I should in the circumstances assume the risk again, and I have the approval of the medical officer of health for the action. Now, Sirs, not only is there considerable difficulty in the correct recognition of the various membranous sore-throats but since joining the profession (I am sorry to say a good many years ago) the typical symptoms of various of the infectious diseases have been more or less altered. For instance, how rarely now do we meet with the fulminating death-dealing scarlet fever epidemics that used to be prevalent? Scarlet fever is now a mild, almost non-pyrexial exanthem. More frequently than not the child has little or no rash, is perfectly well after a couple of days' slight feverishness, and returns to school in a week. Typhoid fever is now as often accompanied with constipation as with diarrhœa, and small-pox as modified by vaccination is almost unrecognisable except by an expert. In these circumstances mistakes do and will occur, giving cause for the uninitiated layman to blaspheme and the profession to be condemned in consequence. Recognising this fact and that the mistakes are not always due to ignorance alone, what means have we as a profession or what means have the various sanitary bodies for the more effectual checking or stopping of these errors and their results? With the profession, of course, the encouragement of more perfect study of the various infectious disorders and the modifications met with will immediately occur to one. With regard to the various sanitary bodies, the provision of shelters for observation, of some provision for bacteriological investigation, for the examination of slides, for the supply of tubes for Widal reaction, the examination and staining of sputum, the supply of antitoxin (how many have done these!), and lastly, the willing coöperation of the medical officer of health in friendly consultation in difficult cases. With regard to the Metropolitan Asylums Board, could not it provide some observation wards where cases of doubtful nature could remain under observation for a few hours and not be pushed straight into the wards? It must be remembered, too, that cases admitted with one kind of disease have been inoculated with others during their stay in these hospitals, so that errors occur inside as well as outside. To lessen the evil effects of these errors and the disrepute that they bring to the profession must be my excuse for ventilating my protest and urging the necessity of finding a remedy if possible. I am, Sirs, yours faithfully,

Kensington, August 5th, 1905. RICHARD BEVAN.

ANATOMICAL PECULIARITIES OF A GALL-BLADDER.

To the Editors of THE LANCET.

SIRS,—The following may be of interest in connexion with Dr. Ferguson Lemon's case of abnormality of the gall-bladder reported in THE LANCET of May 13th, p. 1265. I had occasion recently to make a necropsy on the body of an Italian who was killed by an explosion of dynamite in a mine in this district. On opening the abdomen I noticed that the gall-bladder was apparently absent. On turning up the liver a slight elevation of the usual colour of the gall-bladder was seen on the under surface of the right lobe about two inches from the anterior border. On incision it proved to be a normally sized gall-bladder containing bile, almost entirely embedded in the liver substance. As in Dr. Lemon's case, the coat of the gall-bladder was marked off very definitely from the liver substance but unlike his case was of normal thickness. The cystic duct ran for some distance through the liver substance, emerged at a small fissure of its own near the transverse fissure, and joined the hepatic duct in the usual situation. The fissuring and lobulation of the liver were most irregular but the gall-bladder, liver, and all other organs were quite healthy.

I am, Sirs, yours faithfully,

H. GERALD LOUGHRAN.

Western Australia, July 7th, 1905.

LONDON SANITATION.

To the Editors of THE LANCET.

SIRS,—I desire to bring under your observation a most objectionable and insanitary practice which takes place on six days of the week during the fruit season in London. Carts bring to Covent Garden Market from the surrounding country baskets of strawberries, other fruits, and vegetables, and return to the country with the empty baskets packed with, and in contact with, horse dung and other manure. I have not the least doubt that these same baskets are again filled up the following day with market produce to be brought to Covent Garden and that the same thing is repeated day after day, the only cleansing that the baskets get being probably a washing with cold water, if even that. This practice may be constantly seen on the roads that lead out of London and more particularly on the Hounslow-road.

I returned from West Africa a few weeks ago and was amazed to find this state of affairs, which I understand has gone on for at least several years, in the very centre of civilisation, where one would expect to see sanitation made as perfect as possible. It is ridiculous, almost laughable, to visit a hospital and see the elaborate preparations that are made for disinfecting purposes and then to compare it with this filthy custom. Certainly, camels are swallowed, while gnats are strained at, and one is inclined to ask, Where is the sanitary official? I am, Sirs, yours faithfully,

C. B. HUNTER.

Charles-street, St. James's, S.W., August 7th, 1905.

HOMBURG.

THE PROBLEM OF MINERAL WATER HEALTH RESORTS.—WHAT SHOULD, AND WHAT DOES, DETERMINE THEIR POPULARITY.

(FROM OUR SPECIAL SANITARY COMMISSIONER)

PART I.

THE HOMBURG OF THE PAST.

Bad-Homburg, August 1st, 1905.

THERE is no disguising the fact that of late Homburg has been under a cloud—a light, passing cloud, perhaps, but still a cloud. Yet it is also equally evident that Homburg has never before possessed so many resources for the treatment of various and serious diseases. Why with an increase of facilities and advantages there should be a decrease of popularity is a problem for which there is no one all covering reply. Many causes have been at work and among them political estrangements have played their part. Then there are the ever fickle changes of fashion. One year it is thought "good form" or the "proper thing" to go to some well-advertised resort; and at another time it is some other place that comes in vogue. Where it is only a matter of pleasure and pleasure-seekers this fickleness does not do so much harm but when it is a question of health this is not only regrettable but mischievous. Indeed, in studying the history and the fluctuations in the fortunes of Homburg a big problem presents itself which interests all countries and all places where nature offers some special advantage for the treatment of disease. Too little thought has been given to such questions, too much has been left to mere chance or to the perspicacity of speculators. It is only of late that the State has attempted, at least in some measure, to safeguard the interests of the public. This is notably the case at Vichy. Other places in which the public should be greatly interested have been left almost entirely to rise or to fall according to the length of purse and the ability of certain speculators. Sometimes there have been both ability and money but no agreement as to which form of attraction should be encouraged. This is very generally the case in health stations; it is notably the case at Homburg. Here, as in so many other resorts, we find the two great rival parties. The one seeks to attract visitors by advocating the organisation of innumerable sports, festivities, and pleasures of all sorts; the other party argues that these things are detrimental, that they keep patients away, and that the real welfare of the town depends on the number of cases treated successfully.

So far as the interests of the public at large are concerned the position is very simple. Sports and pleasures do not need the presence of special facilities for medical treatment. Homburg possesses mineral springs of undoubted and exceptional medical virtue; it also enjoys very useful climatic advantages. It is these healing facilities that should be rendered accessible to the greatest possible number of sufferers. Any fluctuation in politics, in fashion, or in financial speculation which prevents the presence of sufferers when their health would be restored by going to Homburg or some other genuine health resort is to be deplored and set down as a public loss. In a word, all that contributes in any marked degree to the relief of disease should be as largely available as possible and no extraneous consideration should step in between the patients and the remedy that they need. Bearing, then, this principle in mind, what has been the history of Homburg? If studied in detail it will show that this resort has owed its prosperity to a fortuitous concourse of very exceptional circumstances rather than to any deliberate effort on the part of any public authority to satisfy an obvious public demand. Perhaps the ancient Romans managed matters better. When this part of the country was annexed to the Roman Empire the natives, said to have been Celts, were making use of the mineral waters to extract salt from them. The Romans did not fail to employ the waters for bathing purposes. The whole country around is rich with Roman remains. Close to Homburg, within an easy tramway ride, under the able direction of Professor L. Jacobi, the Roman fortress of Saalburg has been restored. This is one of the long line of forts that stretched from the Danube to the Rhine and is a great attraction to all who are interested in Roman history and in archæology.

After the departure of the Romans during the dark ages and up to the seventh century but little is known of Homburg. The waters seem to have been used merely for the salt which they contained and which was employed for culinary purposes. In 1622 the Landgraviate of Hesse-Homburg was created under Prince Frederick I. His successor, Frederick II., known as the Silver Leg, enlarged the town and built its present castle or princely residence. In 1766 the Landgrave Frederick Lewis came to power and by devoting especial attention to the mineral springs laid the foundation of the town's future renown. He also succceded in attracting various celebrities to live at, or to visit, Homburg. But these German princes were notoriously poor and could not do much. The next Landgrave, Prince Frederick Joseph, was, however, fortunate in marrying in 1818 Princess Elizabeth of England, one of King George III.'s daughters. This princess brought with her a settlement of £10,000 a year which was a substantial addition to the 20,000 or so florins which constituted the civil list of the Landgrave. The Princess Elizabeth made herself very popular and for this reason the principal spring at Homburg was named the Elisabethbrunnen. Gardens and walks were laid out, old houses were pulled down, and a deliberate attempt was made by the reigning family to render the mineral waters available for the treatment of disease. These efforts so far succeeded that it became worth while to keep a record of the persons who were now beginning to resort to Homburg for their health. The first such record is dated 1834 and in that year there were 155 visitors. The following year there were a few more; but in 1836 there were 294, and in 1837 no less than 800. In 1839 the maximum figure under the *régime* of the Landgraves was reached—namely, 829.

There now happened the event which has had the greatest effect over the destinies of Homburg. It is impossible to consider this fact without feeling much concern and doubt. Ought the interests of public health to depend to such an enormous extent on other and far less estimable considerations? In 1841 the Landgrave Philip, who had now succeeded to the Landgraviate, concluded a contract with Messrs. Louis and François Blanc conceding to them the right to establish gaming tables at Homburg. At first this did not make much difference. The brothers Blanc had very little capital. They put their roulette tables in a small building, now converted into an institute for mechano-therapeutics, and situated behind the row of jewellers' shops near the Kaiserbrunnen drinking fountain. But an incident soon occurred producing material consequences from which the inhabitants of Homburg still suffer. The Kurfurst von Hessen, who had a castle and an orangery in the neighbouring town of Hanau, was one of the earliest patrons of the roulette and he soon contrived to lose 100,000 gulden. This was the commencement of the fortune of the Blanc brothers and represented a much larger sum than the capital with which they had started. But what affects the town of Homburg to this day is the fact that the Kurfurst von Hessen having lost this sum proceeded to borrow money so as to try to win it back. In those days it was the fashion for princely families to rear orange trees and those at the castle of Hanau were celebrated for their splendour. Nevertheless, they were handed over to the Blanc brothers as a pledge in exchange for a loan of 40,000 gulden. But before this pledge was redeeemed their owner died and his son on succeeding to the estate claimed the orange trees back again. As, however, he could not pay the money which had been advanced they were not returned. The new Kurfurst von Hessen was much angered and it so happened that just at that time plans had been made to connect Homburg with Frankfort by a railway which would pass through some of his estates. The scheme was emphatically rejected. The railway nevertheless was built but having to avoid the estates in question has to follow such a roundabout course that the journey is twice as long as it need have been. For more than half a century countless thousands of people have had to perform a half-hour's journey when, but for the squabble over the orange trees and a gambling debt, 15 minutes would have sufficed. Further, it may be noted that while this dispute was proceeding the orange trees began to sicken and would probably have died if they had not been bought by the late Empress Frederick, then Crown Princess of Prussia, for her garden at Kronberg. Here they were restored to health by the science and skill of the gardener. It is on such incidents as these that the fortune of Homburg has depended, yet it should be based exclusively on the medical qualities of its waters, on its climate, and on the efficacy of its sanitary laws and administration, together with the comforts and accommodation available for patients and visitors.

After the first struggle and when once the winnings of the bank at roulette had accumulated sufficient capital to face all contingencies, the fortunes of Homburg and the Blanc family became identical and went up by leaps and bounds. In 1842 there were 1732 visitors and in two years this number was doubled. In 1847 there were 5187. Speaking of 1848, Heine said: "There comes a time when every monarch is feeling his head to see if his crown is still on it," and this insecurity caused a falling off in the number of visitors but the figures rose again in 1850 and attained 10,105 in 1856. At this they remained and 10,000 may be considered as about the average till 1865, when there were 12,473 visitors. Then was reached the eve of another great crisis in the fortunes of Homburg.

It must not be thought that the gambling alone attracted this increase of visitors. The ability, the enterprise, and the perspicacity of the Blanc brothers are well known, and as an authority on complex financial problems M. Louis Blanc elicited the praise of the late Lord Brougham when he came in contact with him on the Riviera. To make Homburg attractive the Blanc brothers lavished their money on improving the town. They built a palatial Kurhaus or Casino and soon found that it was not large enough and therefore added two wings, in one of which they built an elegant theatre. The cornfields behind the Casino were converted into a beautiful park, with lake, swans, and various picturesque attractions. Better still, deep borings were made for the mineral springs, to secure them against contamination and to increase the quantity and the trustworthiness of the supply of mineral water. Foreign medical practitioners were encouraged to settle at Homburg. There were one French, one Dutch, and two British medical men to attend to patients of various nationalities. The building of churches for various denominations and nationalities was likewise encouraged. If most of the people who came gambled it was entirely their own fault. Those who were wise enough not to play gratuitously enjoyed all the advantages that were offered.

There were, of course, evil sides to all this prosperity. For instance, the more the Blanc brothers did the less the town was disposed to undertake. Now although, to prosper the roulette, money was freely spent on theatricals, concerts, bands, fireworks, illuminations, parks, sports, casino buildings, and so forth, nevertheless it was scarcely to be expected that the Blanc brothers would devote the proceeds of the gaming tables to the carrying out of a scheme of drainage or of works to provide a well-protected, ample, and pure water supply. The houses and the hotels were then drained into cesspools which were built anyhow, were not properly cemented or ventilated, and were very generally in a leaky condition. Indeed, a case is related of a large part of the contents of a cesspool pouring out into the kitchen of a first-class hotel just at the moment when the *table d'hôte* was being served. There were some cases of typhoid fever in this hotel and in several other parts of the town. Yet in these old days when the accommodation for visitors was very insufficient and when the general conditions were most insalubrious there was a brilliant crowd. Royal princes and crowned potentates flocked to Homburg and with them the leaders of fashion and the queens of beauty. But the days of gambling were numbered.

The war between Prussia and Austria broke out in 1866 and one result was the annexation of Frankfort with all the surrounding country, including Homburg. There is no longer a Landgrave of Hesse-Homburg, now Homburg is simply a town in the Kreis or district of Ober Taunus and a portion of the kingdom of Prussia. But the Prussian Parliament had altogether abolished gambling. Considering, however, the vested interests that had grown up in Homburg the new Government was willing to give a fairly long notice to quit, though this was done only on condition that an enormous tax should be paid. Previously the town derived only indirect benefits from the gambling, as but a small tax was levied on the Casino. The tables were to be allowed to continue till Dec. 31st, 1872, on condition of paying an annual tax of £24,000. Then a great and final effort was made and the rush of visitors increased as the last moments approached. In 1869 they numbered 19,843. Even during the Franco-German war of 1870 there were 10,841 visitors. In 1871, in spite of the after-effects of the war, there were 18,067, and it was during the last year of all that the zenith was reached when no less than 21,001 persons visited Homburg. But when the last marble had been spun for the last time round the roulette it seemed as if the wheel of fortune had for ever been broken. Hotel-keeper and shop-keeper looked upon their establishments as useless and those who had not yet made their fortunes considered themselves as ruined.

There was, it is true, a faint flicker of hope. The tax which the Prussian Government compelled the owners of the tables to pay had been carefully hoarded up and there remained some £150,000 in hand for which 5 per cent. interest could be obtained in those days. Thus the town saved a permanent endowment out of the wreck of the roulette. Then there were the Casino itself and its magnificent park and gardens, to say nothing of the fact that the appurtenances of the mineral springs had been much improved, and all out of the profits derived from the roulette and the trente et quarante tables. Still it was quite evident that the French visitors who had done so much to render Homburg attractive would not come after the war, particularly as there were no more gaming tables. The Russians would not come, nor the Italians, nor wealthy persons from South America; in fact, it seemed as if no one would come at all unless it were a few English. Thus, and under these depressing anticipations, what may be qualified as a new Homburg, a modern Homburg, came into existence. It is the new, the modern Homburg that may justly claim to interest the medical profession. But when the history of ancient Homburg, the Homburg of a generation ago, is taken into consideration the question arises whether it is right that such valuable mineral springs should have to depend for their popularity on such antecedents. Should there not be some sort of official and scientific body or organisation to make known what is really valuable to humanity, instead of having to wait as was the case with regard to Wiesbaden, Baden Baden, and Homburg, for the advent of the enterprising owners of roulette tables?

(To be continued.)

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Monyhull Hall.

THE estate of *Monyhull Hall*, comprising in addition to the hall, a lodge, cottages, stables, outbuildings, and 174 acres of land, is shortly to be put to the purpose for which it was purchased—viz., a home for epileptics and feeble-minded individuals. The management is in the hands of a joint committee of the Birmingham, Aston, and King's Norton boards of guardians and accommodation will at first be provided for 110 patients from Birmingham, 50 from Aston, and 50 from King's Norton. The inmates will be engaged in agricultural pursuits. No one over 45 years of age will be eligible for admission and the necessary precautions will be taken to prevent them propagating their species; children will be left to the care of the education authority. Feeble-minded children on reaching the age of 16 years leave the special schools and it is to provide the extra care and protection necessary after that age that the scheme has been brought forward. The estate cost £100 per acre and although it is not expected that the colony will be self-supporting it is believed that the earnings of the inmates will reduce the cost of their maintenance. The estate is estimated to afford ample room for the erection of as many cottage homes as will be required during the present century. Two other schemes which the boards of guardians have had under consideration for some time—viz., a labour colony for the unemployed and a special home for the "ins and outs"—have been lately discussed and a definite resolution has been arrived at not to proceed further with them at present. The objection to both schemes has been based largely on the ground of economy.

The Birmingham and Midland Eye Hospital.

The seventy-fifth annual meeting of the friends of the above charity has lately been held. Although there has been a slight diminution in the annual subscriptions, still the item of legacies, due largely to the generosity of the late Mr. Richard Cadbury, amounted for the year to £5887 and the treasurer has been able to show a balance carried forward and partly invested of £13,664. The expenses for the year showed a decrease due to the smallness of the item of repairs and alterations. During the year 26,831 patients had been treated, of whom 1100 were in-patients, and since the foundation of the hospital in 1823 the number of patients admitted amounted to 782,557. During the last year the average number of beds occupied nightly was 73·6 and the average length of stay in hospital was 24·4 days. The number of operations performed on in-patients was 676, including 350 for the removal of cataract, 202 iridectomies, and 85 extirpations of the eyeball. In the out-patient department 637 operations were performed. Spectacles were supplied in 8979 cases and foreign bodies were removed from the ocular surfaces in 8428 cases. The Earl of Dartmouth was elected president for the ensuing year.

Lead Poisoning in the Pottery Trade.

A Parliamentary return has lately been issued relating to lead poisoning in earthenware and china works. The North Staffordshire return relates to 318 factories. In the Potteries 84 cases of lead poisoning were reported compared with 204 in 1899. The proportion of cases to persons employed in lead processes in the Potteries is 0·9 per cent. of males and 3 per cent. of females.

The Pollution of the Trent.

The reply of the Stoke town council to the letter addressed to it on the above subject by the Duke of Sutherland, to which I referred in my last letter, has just been published. In it the council states that it thoroughly sympathises with the duke as the council itself is a fellow sufferer. The council alleges that the pollution of the Trent and its tributaries takes place higher up the stream and it expresses the opinion that there would be little or no cause for complaint if all the other authorities put into the stream as good effluents as those from the Stoke sewage farm. Copies of remonstrances addressed by the council to neighbouring local authorities with regard to the pollution of the streams were inclosed with the reply. The letter further admits that within the last few months some pollution of the river has taken place but points out that this is owing to the breaking of the Campbell-road sewer by the mining operations of the Stafford Coal and Iron Company of which the duke is one of the largest shareholders. At the request of the company the council was making temporary arrangements until such time as the mining company's engineers were of opinion that the subsidence had ceased. However, the corporation, to show its *bona fides*, had decided to take steps to lay down a new iron-pipe sewer without waiting any longer. It has also decided, although it considers its effluent to be a fair one, to call in an expert to advise it on the whole matter. It further asks for specific information as to when and where the Stoke effluent had been turned into the river so as to cause the pollution complained of. The corporation of Newcastle-under-Lyme seems to be at present responsible for some part of the nuisance, since a huge volume of sewage matter is flowing down the Lyme brook from the Dimsdale sewage farm owing to the dam being broken. With these two exceptions, however, none of the local authorities are willing to admit any responsibility for the pollution, pointing to the money that they are expending in experimental works. The local authorities in North Staffordshire are at present actually pledged to the expenditure of £220,000.

The Birmingham Education Committee.

At the last meeting of the above committee the annual report of the special schools after-care subcommittee was approved and directed to be printed and circulated. The chief conclusions arrived at in the report were (1) that a certain percentage of mentally defective children should be educated in board schools to insure sufficient industrial training and to remove those who were known to be moral imbeciles from an environment which must necessarily lead to anti-social conduct ; and (2) that industrial colonies sh be established where cases which will never become supporting or morally responsible in ordinary circumsta may be placed under such supervision as will enable the contribute to their own support. Mrs. Pinsent, in movin adoption of the report, thought that in time they woul able to turn out 30 per cent. able to earn their own li since they were now attempting to educate in special cl children of a higher mental capacity than when the sch were instituted four years ago. At that time there were about 100 children so educated, the majority of whom almost imbeciles. An interesting statement in the re was that there were 206 epileptic children in the city an these all but 20 suffered in so slight a degree that they c be educated in the day schools under ordinary conditions by ordinary methods.

The Health of Birmingham.

The health of the city still remains good despite the that owing to the great dryness and heat there has bee outbreak of diarrhœal complaints. A significant fac connexion with deaths from diarrhœa is that practic all of them occur in the families of the working cla Further, amongst babies under six months old, fed natura 8 per 1000 died, while of babes not naturally fed 252 1000 died, or more than 30 times as many. Three fi cases of small-pox have been notified and the numbe cases of scarlet fever is slowly increasing, although they happily of a mild nature.

August 8th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

University of Liverpool: Award of Robert Gee Scholarsh

Two Robert Gee scholarships, each of the value of £ tenable for one year, have been awarded to Joseph Bamfo Warrington Grammar School, and Idwal J. Williams, H head County School. The successful candidates must regis as medical students in October and attend the clas required for the first year's study for a medical degree of University of Liverpool. The scholarships, which are f in number, are among the benefactions bequeathed to university by the late Mrs. Gee, widow of Dr. Robert G formerly physician to the Liverpool workhouse. The schol ships are only open to male students and to those who h not attended day classes at the University.

Munificent Bequest to the Delamere Forest Sanatorium.

The trustees of the late Mr. James Holden of Marslan near Rochdale, have made a grant of £10,000 to the Delam Forest Sanatorium for Consumption. One of the conditio is that six beds shall be set apart for the exclusive use Rochdale patients. Some time ago an influential Rochd deputation waited upon the trustees to ascertain wheth it were possible to make a grant to an institution the treatment of consumption at Rochdale, but that ins tution could not comply with the terms of the will, whi states that the money can only be given to well-establish institutions. The proposed grant to the Delamere Fore Sanatorium was then put forward as an alternative schem The total bequests to charities of the late Mr. Hold amounted to £250,000.

Liverpool Royal Infirmary: Appointment of Assistant Gynæcological Surgeon.

The newly created post of assistant gynæcological surge at the Royal Infirmary has been filled by the appointme of Dr. W. Blair Bell. There were four candidates for t election committee to choose from, two being local men a two from London.

Liverpool Institute of Tropical Research.

The initial meeting of the council of the Liverpo Institute of Tropical Research was held on August 2n when Sir Alfred Jones, K.C.M.G., was unanimously electe chairman. Viscount Montmorres was appointed the direct of the institute and Dr. Eric Drabell the economic botanis The following gentlemen were appointed to act as a pr fessional board: Professor E. C. K. Gonner (statistics Professor Harvey Gibson (botany), Professor W. A. Herdma (zoology), Professor B. Moore (physiological chemistry), an Professor Ronald Ross, C.B., F.R.S. (tropical hygiene an itation). At the end of the meeting the chairman nounced that Mr. W. H. Lever had promised a similar arantee to his own—£1000 a year for four years—that Mr. Sutton Timmis would contribute £250 a year, Mr. John nkin £250 a year, and Mr. H. Sutton Timmis £50 a year.

August 8th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

The North Devon Infirmary.

THE annual meeting of the governors of the North Devon nfirmary at Barnstaple was held on July 25th, the Lord ieutenant of the county (Viscount Ebrington) presiding. he report stated that during 1904 the in-patients numbered 92, against 840 in 1903, and that there were 4014 out-atients treated as compared with 3032 in the previous year. he average daily number of in-patients was 53. The nancial statement showed that the receipts amounted to £2593 and that the expenditure was £2510. It was decided o make several structural alterations in the building so as o provide accommodation for 50 additional beds, 16 being or men, 20 for women, and 14 for children.

The Sale of a Medical Practice in Bideford.

Allusion has been made in THE LANCET[1] to litigation connected with the transfer of a medical practice in Bideford. Dr. Alexander Lane sold the practice to Mr. C. Pearson who subsequently brought an action against Dr. Lane, when the jury gave a verdict in favour of Mr. Pearson or £200. Dr. Lane subsequently became bankrupt in Newcastle-on-Tyne, whereupon the judge of the Newcastle County court granted him an immediate and unconditional discharge. An appeal against this decision was heard by Mr. Justice Bingham and Mr. Justice A. Lawrence on August 1st. Mr. Justice Bingham in giving judgment said that Mr. Pearson had not received a penny of the £200 which through the finding of the jury ought to have been paid to him by Dr. Lane; this was a state of things which the legislature distinctly said was not to be. His lordship added that Dr. Lane was not entitled to his discharge and the appeal against the decision of the Newcastle county court judge was upheld. Mr. Justice Lawrence agreed and the appeal was allowed, with costs, an order being made for the suspension of the discharge of Dr. Lane for two years.

The Appointment of Medical Officer of Health for Wrexham.

The Wrexham rural district, which has a population of 6,000 and an area of 65,000 acres, has two medical officers of health, following the custom which at one time was very common of appointing the Poor-law medical officers as medical officers of health. An endeavour is being made by the Local Government Board to put an end to this undesirable duplication of officers under one authority and one of the recommendations of Dr. L. W. Darra Mair, made after an inspection of the district two years ago, was that at the first opportunity an effort should be made to appoint one officer who should devote his whole time to his duties. The death in March last of Mr. R. W. J. Evans, the medical officer of health of Wrexham borough, has led the rural district council to suggest the appointment of a medical officer of health for the two districts at a salary of £500 per annum. The combined population is over 70,000. When the proposal came before the town council it met with some opposition, one member arguing that the size of the district was so great that it could not be efficiently covered by one official. No decision was come to in the matter and the question will be discussed again in September.

Llandrindod Wells.

The large common of about 50 acres, which adjoins the pump rooms at Llandrindod Wells, has been in danger of being given over to builders, and those who drink the waters have been perilously near being deprived of a breezy open space in which to take their ten minutes' walks between drinking each glass of saline or sulphur water. The district council has succeeded, though with some difficulty, in getting a Bill through both Houses of Parliament enabling them to purchase the common and to secure nearly all of it as an open space for ever.

Lunacy in Herefordshire.

Mr. C. S. Morrison, the medical superintendent of the Hereford County and City Lunatic Asylum, in his annual report to the committee of visitors points out that Hereford can claim to be among the first to have recognised and to have provided for the more humane treatment of the insane, for as long ago as the year 1798 there was in the city a hospital for the mentally afflicted which had been founded by the private munificence of the few and was maintained by public charity. There are, it appears, certain endowments from this hospital which are administered by the governors of the general hospital and £10 yearly are given to the asylum committee to be used by them in aiding deserving patients when leaving the institution. Mr. Morrison suggests that the fund might be used for the maintenance of a special department of the hospital in which the early treatment of incipient insanity could be carried out.

Isolation Hospital Treatment in Newport.

The town of Newport (Mon.) is well provided with isolation hospital accommodation and this is made good use of by the inhabitants. During 1904 there were 259 cases of scarlet fever notified to the medical officer of health and of these 84 per cent. were treated in the hospital, while 71 per cent. of the patients suffering from typhoid fever and 60 per cent. of those suffering from diphtheria were also removed there. Since the extension of the hospital two years ago the town has been comparatively free from epidemics of these diseases and Dr. J. Howard-Jones, the medical officer of health, suggests that one of the small blocks should be used for the reception of early cases of pulmonary tuberculosis among the poorer classes of wage-earners who cannot afford to pay the fees which are charged in other sanatoriums. He considers that as the capital outlay would be small and as the administration charges have to be paid in any case the cost per patient would not exceed one guinea weekly.

August 7th.

LEEDS.

(FROM OUR OWN CORRESPONDENT.)

The Professorship of Surgery at the University of Leeds.

Mr. Edward Ward, who has held the professorship of surgery for the past six years, has resigned and the council, in accepting his resignation, has expressed its sense of the loss which the University has sustained in the limitation which this will impose on his teaching. I say "limitation," for happily Mr. Ward, who is senior surgeon to the infirmary, retains his post as clinical lecturer on surgery and as such is a member of the Faculty of Medicine. The council is to be congratulated on its choice of a successor and Mr. Harry Littlewood, M.Sc. Leeds, F.R.C.S. Eng., will, I feel confident, maintain the high standard of teaching which his predecessors have set. Mr. Littlewood began his connexion with the school as honorary demonstrator of surgical pathology and for the last six years has been the lecturer on practical surgery. His promotion causes a vacancy, therefore, which the council intends to fill up at a subsequent meeting.

Airing Grounds for Patients of Hospitals.

The use which is made as airing grounds for the patients of the open spaces, small though in many cases these may be, which are attached to the various London hospitals is familiar to all who visit these institutions, but probably there are few other than those who have been resident officers who are aware of the extent to which the terrace of the Leeds Infirmary is utilised for this purpose. This "terrace," which can only be seen from the surrounding thoroughfares at one or two points, forms a means of communication between the upper part of the five ward pavilions originally designed by Sir Gilbert Scott and provides a fairly extensive and elevated airing ground or balcony. It is now intended to provide means of access to this from the upper ward of the large new pavilion, which formed a part of the great extension of the infirmary carried out some 12 years ago. Plans have been prepared by Mr. Sidney Kitson and approved by the board which show a covered terrace or elevated corridor passing from No. 18 Ward to an extension of one of the three sides of the existing "terrace" which will be converted into a shelter.

---

[1] THE LANCET, Feb. 18th (p. 465) and July 1st (p. 55), 1905.

Depôt for the Sale of Pure Milk.

It was announced some time ago that the Leeds corporation had decided to institute a depôt for the sale of pure milk by making an arrangement with a farmer to purchase all his milk subject to his observing certain stringent conditions as to the regulation of his dairy. This announcement, it is now found, was premature, for when the recommendation of the sanitary committee on which it was based came up before the city council for confirmation it was ruled that it was not in harmony with statute that the recommendation should be carried out. The opinion is held by some that certain corporations that have instituted such depôts are acting *ultra vires* and some think that Leeds might have followed suit and risked being pulled up. The lord mayor, who gave his ruling after careful consideration and consultation with legal authorities, has shown his sympathy by subscribing £200 towards the expenses of instituting such a depôt and no doubt the necessary sum will be readily secured. It is understood that the corporation intends to apply for powers to institute and to carry on such a depôt and it is gratifying to find that there is a practical certainty of the work being meanwhile carried on by voluntary effort.

August 8th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Inebriate Homes in Scotland.

IN his report on the Inebriate Homes in Scotland Dr. J. C. Dunlop, who is inspector for Scotland under the Inebriates Acts, deals with Girgenti. This reformatory is managed by a committee of the Glasgow town council and certified for the reception and treatment of 58 women convicted under Sections 23 and 24 of the 1898 Act. It has now been in existence for four years and to it 88 inmates have been admitted. On Jan. 1st, 1904, there were resident in the reformatory 39 inmates, absent on licence 18, and absent without leave (having escaped from the reformatory or absconded from guardians when out on licence) 10—in all 67. During the year 10 women were admitted, 29 were discharged at the expiry of sentence, four were transferred to the State reformatory, and one died. On Dec. 31st there were in residence 27, out on licence nine, and absent without leave seven, making a total of 43. The daily average number in residence in the reformatory during the year was 38. While stating that the amount of reformation resulting from treatment in this reformatory is small, Dr. Dunlop does not consider that it is in any way indicative of failure on the part of the institution, for the functions of these reformatories are twofold, the cure of the inebriate and the segregation of the inebriate, and if the reformatory fails to fulfil the one function entirely it is nevertheless useful in that it can, and does, fulfil the other. This second function, the segregation of drunken pests, is a most useful and beneficial one, and is one which perhaps the managers of this reformatory might give more credit to than they have recently done. If the managers would consider their reformatory as a means for preventing the spread of drunken habits in the town as much as, if not more than, a means of curing the degraded drunkard and would use it accordingly then the present useful functions of Girgenti Reformatory would be greatly enhanced. Let them look to their reformatory as an institution comparable to an infectious diseases hospital, an institution founded to serve a double purpose, the treatment of the sufferer and, in addition, the safeguarding of others. The cost of maintaining Girgenti Reformatory during the year has amounted to £2747 12*s.* 6*d.* Of this sum £1084 7*s.* 6*d.* were contributed by the Treasury; £4 14*s.* 10*d.* were received as payment for work done by the inmates; and the balance of £1650 11*s.* 5*d.* was paid by money collected by assessment in Glasgow. During the period under consideration at the Greenock Reformatory the average daily number of convicted persons in residence was 18·3; but in addition to these there was a considerable number of voluntary inmates. The convicted cases were all confirmed inebriates and most of them had been so for years. The ages of the 15 admitted ranged from 21 to 48; their mental state as reported by the medical officer was good in only five cases, in four it was moderately good, while in six it was decidedly weak if not actually insane.

The Marine Biological Association of the West of Scotland.

This association is now holding its summer classes for teachers in marine biology. The "A" course finished last week and the "B" course commences this week. The first course includes description and dissection of certain types, external examination and identification of the remaining types, and demonstrations in the tank-room. The second year's course is chiefly taken up with the mounting of selected specimens which remain the property of the students. To this is added in the third year's course instruction in the systematic zoology of special groups. The steam yacht *Mermaid* is used for dredging excursions, and those who are taking advantage of the facilities placed at their disposal find that they are enjoying a pleasant holiday and at the same time acquiring a considerable store of knowledge. In order to encourage the study of this interesting subject certain of the school boards in some instances are paying the necessary fees.

Cottage Hospital for Port Glasgow.

At a recent meeting of the magistrates of Port Glasgow Mr. John Birkmyre intimated that he and his wife had decided to gift £10,000 to the burgh for the erection of a cottage hospital. A suitable site behind Chapelton school has been granted by Sir Hugh Shaw Stewart at a minimum feu-duty. The hospital is to be composed of two wards and to contain 22 beds. In the event of the whole £10,000 not being required for building purposes the balance is to be used as the nucleus of an endowment fund.

Swimming and School Boards.

The lessons in swimming provided by the Glasgow school board to the boys in the higher classes are much appreciated and the results are highly creditable. Over 600 boys were tested from 20 different schools and 90 per cent. of the boys who have had two lessons per week during the last eight weeks were able to swim satisfactorily, while 50 per cent. of those receiving one lesson per week were able to swim fairly well. To any reader of the newspapers during the summer months when so many drowning accidents occur this action of the school board will seem highly commendable and should eventually if persisted in result in the saving of many valuable lives.

August 8th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Apothecaries' Hall of Ireland.

AT the annual meeting of the governor and council of the Apothecaries' Hall of Ireland held on August 1st the officers were elected for the ensuing year. The *personnel* of the council remains much as before but Lieutenant Colonel F. G. Adye-Curran, M.D. Dub., F.R.C.S. Irel., was duly elected governor and representative on the General Medical Council for the coming year.

Epizootic Lymphangitis in Ireland.

The alarm caused by the epidemic of glanders among horses in Ireland has been somewhat allayed by an official statement from Colonel Davidson, A.Q.M.G. Irish Command, Royal Hospital, Dublin, stating that the disease which first appeared at the Curragh camp in last November was effectively checked by the preventive measures adopted, the total number of cases having reached only 42. The horses from the large districts of Waterford and Kilkenny are, however, prevented from being sent to the coming horse show held by the Royal Dublin Society, which latter constitutes both from the economic and social points of view the most important annual festival in Ireland. The recent discussion in the House of Lords shows the importance of the matter.

Health of Dublin.

A fair index of the zymotic health of Dublin is generally to be found in the records of the monthly meeting of the governors of Cork-street Hospital. On July 13th the medical superintendent reported that during the month of June there was a large increase in the number of cases of pneumonia of a severe type admitted to the hospital, scarlet fever and diphtheria contributed a fair share of the deaths, while cases of measles declined considerably. The admissions of enteric fever cases were not numerous but they were nerally of a severe type. There has been much comment the exceptionally dry weather which has recently pre-iled in Dublin and in Ireland generally. The governor of the yal Botanic Gardens, Glasnevin, has reported that during three months ending July 31st, 1905, the record of rainfall the district has been unusually low, the season having oved the driest since 1887—the jubilee year.

Health of Belfast.

At a meeting of the city council held on August 1st it was ported that measles is again more or less prevalent in lfast, 17 deaths having been caused thereby. Between ne 18th and July 15th there were notified 178 cases of motic disease; 65 cases of simple continued fever; 32 typhoid fever, 26 of scarlet fever, 24 of erysipelas, of diphtheria, four of croup, and one of small-x. The annual death-rate was 17·1. Diarrhœa is o very prevalent, having caused 26 deaths in the t month. A deputation appeared before the council presenting the inhabitants of the Shore-road and the rth-East district of Belfast to condemn the system of cteria beds, urging that there should be no more outlay d that a thorough investigation should take place into the oper method to be adopted. Finally they protested against discharge of sludge upon the beach in the neighbour-od. In reply it was stated that the bacteria beds worked isfactorily in Belfast and the last bed put down, which s somewhat of an improvement on the former ones, was rifying to the extent of 96 per cent. the sewage passing rough it.

Down District Asylum.

The report for the year ending Dec. 31st, 1904, has just en published. 179 cases were admitted during the year d there were residing in the institution on Dec. 31st 0 inmates—284 males and 316 females—the total cases der care during the year being 451 males and 391 nales. There were 84 discharges, the percentage of coveries on admissions being 41·9. With the possible ception of dysentery there was no disease due to local con-ions and this affection is reduced in frequency and in erity of type. The inspector of lunacy in his report has pressed "entire satisfaction" with the institution and he ide no suggestion for improvements which would entail y considerable expense.

Death of Mr. John Auterson, L.R.C.P. Edin.

On the night of August 5th as Mr. John Auterson, a well-own medical practitioner of Cookstown, co. Tyrone, was urning home from paying a professional visit in the country horse shied at the reflection of a lamp on the white-shed gable of a house on the road. The animal ran back d the vehicle with Mr. Auterson was precipitated into a bog feet below. The road at the place and for many yards is tally unprotected, not even a wire fence or hedge being ovided at a place where the bog has been gradually cut ay to provide firing by the use of the peat (or turf as it is lled in Ireland). The accident was fortunately seen and r. Auterson was removed to an adjacent house where Mr. R. rgess (Coagh) and Dr. C. H. P. D. Graves, Dr. W. J. R. ight, and Mr. R. Crossett (all of Cookstown) did every-ing in their power for their injured *confrère*. On the ening of the following day Mr. Auterson was removed to s own house where he died on August 7th. The deceased ntleman, who was born at Coolsaragh, Desertmartin, came in 1868 L.R.C.P. Edin., and practised at first in aperstown but 30 years ago removed to Cookstown, where built up a large practice and was greatly liked by the blic and his professional colleagues. He was unmarried d leaves a brother, a medical practitioner, in Magherafelt.

August 8th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

ction of Metallic Ferments on the Blood Cells and on the Production of Uric Acid and Urea.

IN THE LANCET of Dec. 24th, 1904, p. 1816, an account as given of some investigations made by M. Albert Robin owing that metabolic processes in animals might be odified by hypodermic injections of fluids containing a nute amount of certain metals in a state of extreme sub-vision. The metals in question were palladium, gold, ver, and platinum; their effects were shown by alterations in the quantitative composition of the urine and in the amount of carbon dioxide excreted and the name of "metallic ferments" was given to the solutions possessing this property. At a meeting of the Academy of Medicine held on July 18th M. Robin read a paper describing further observations which he had made on the same subject in conjunction with M. Émile Weil. He said that they had examined the effects produced by the metallic ferments on three patients suffering from subacute articular rheumatism or cancer of the stomach. The excretion of urea and uric acid and the assimilation of nitrogen were always increased with simultaneous production of leucocytosis and intense leucolysis. They had endeavoured to discover the origin of the uric acid thus produced and eliminated in excess. It was well known that uric acid was supposed to be derived from nucleins set free and decomposed in the organism as a result of the destruction of the white corpuscles of the blood, but in the present cases the polynuclear neutrophiles must be regarded as the source of the uric acid that was eliminated. It was to be remembered, however, that leucolysis and the formation of uric acid were not uniformly associated and might be brought about independently of one another by the use of certain drugs. It was obvious therefore that uric acid had no immediate and invariable connexion with the destruction of leucocytes but that it might arise from other causes influencing the hæmopoietic organs. To explain the observed facts M. Robin and M. Weil have suggested an hypothesis of which the following is an outline. The leucocytes are the carriers of the soluble organic ferments; these ferments when set free by leucolysis exercise a deoxidising action in the organism and give the first impulse to the processes which result in the formation of urea and uric acid. If, however, the ferments do not cause the elimination of uric acid, as is the case in cancer and cachexial diseases, it is probable that the leucocytes contain no diastase because destruction of the leucocytes is not followed by the ordinary results of the liberation of diastase. Whatever may be the value of this hypothesis the observed facts which it endeavours to explain at least deserve to be recorded.

Neuroses of Childhood and the Education Problem.

At the same meeting of the Academy of Medicine M. Maurice de Fleury described 37 cases of idle, inattentive, mentally depressed, and unruly children who were neurasthenic, arthritic, hysterical, and mentally deficient, with some indications of chorea and diabetes. An improvement followed on the use of appropriate treatment. M. de Fleury said that the physical conditions reacted on the moral conditions in children as well as in adults, a circumstance which justified medical treatment even when the disorder was apparently an intellectual perversion (*maladie de l'esprit*). Many troublesome school children upon whom punishment had no beneficial effect were found when carefully examined to be the subjects of either definite neuroses or nutritional diseases. The results of medical treatment showed that the association of these conditions was not a mere coincidence but that they were mutually related as cause and effect. The treatment required to be supplemented by intellectual and moral re-education.

Tetanus of Uterine Origin.

At the July meeting of the Société d'Obstétrique, de Gynécologie, et de Pédiatrie Dr. Ris described a case in which the patient was a primipara, 18 years of age. She was at first attended by a midwife, an elderly woman, but a medical man had to be sent for, who found that labour had been in progress for 48 hours, that the shoulder was presenting, and that the fœtus was dead. Dr. Ris decided to perform embryotomy by the method of Dubois. The uterus was in a state of tetanic contraction and rupture of it occurred as soon as the operation was attempted. Dr. Ris thereupon immediately performed Porro's operation. The patient's condition was favourable until the evening of the twelfth day, when her temperature rose slightly and her neck became stiff. The ordinary symptoms of tetanus afterwards appeared and she died suddenly. Fluid from the cervix contained the bacillus of tetanus in pure culture.

White Swelling of both Knees.

At a meeting of the Surgical Society held on July 26th M. Walther showed a man, 20 years of age, who when in his tenth year was found to have a white swelling of his left knee. Recovery followed after some months but the joint was ankylosed at a right angle. Last November the young man came under the care of M. Walther with a white swelling of the right knee. Orthopædic resection was necessary for the left knee, but as a double resection would have condemned the patient to walk with crutches for the remainder of his life M. Walther treated the right knee by the sclerogenous method (interstitial injection of chloride of zinc). The joint is now moveable and the man can walk very well.

The Relative Merits of Rapid and Slow Methods in Surgical Operations.

At a meeting of the Surgical Society held on July 27th M. Doyen delivered an interesting address on Rapid and Slow Methods of Operating. He said that prolonged operations had come into use since the discovery of the means of producing anæsthesia and preventing sepsis. The earliest of the prolonged operations were those in which the écraseur of Maisonneuve and Chassaignac was employed. The inventor of the serre-nœud aimed at the prevention of purulent infection. At the present time the rapid and slow methods had each their respective advantages. Most operations consisted of two distinct stages, the first being the removal of the affected part (*exérèse*) and the second being the procedures preliminary to closing the wound (*réparation*). The first stage ought to be accomplished in the least time possible so as to avoid loss of blood and to diminish surgical shock. The second stage, on the other hand, required both time and care in order that a good result might be secured. It was only by following a simple and definite method that the affected part could be removed both quickly and well. Skilful management of the first stage tended to simplify the second stage. In some instances the whole of an operation might include no more than one of the two stages already mentioned; for instance, the removal of large naso-pharyngeal polypi consisted only of the first stage and operations for fistula only of the second stage. Gastro-intestinal operations consisted principally of the second stage, because the removal of the affected part required minute precautions and complicated procedures. Every surgeon ought to possess manual dexterity and presence of mind sufficient for the rapid performance of such stages of an operation as should not be prolonged; he would then be able to give the necessary time to the ligatures, the sutures, and the closing of the wound. The future in surgery would belong to the most skilful and to those who followed the best methods.

Reflex Facial Movements.

At a meeting of the Medico-Chirurgical Society held on July 10th M. Maurice Bloch said that it was common enough to see the features of patients distorted with pain, but on carefully observing this reflex he had observed that it sometimes appeared on the side opposite to the seat of the pain. A man suffering from intestinal pain on the right side had facial distortion on the left side. Another man suffering from crural neuritis made spasmodic movements with the orbicularis muscle and the eyelids of the opposite side. This fact was an additional proof of the decussation of the sensory nerves and the close connexion of the sensory and motor fibres in the same cerebral hemisphere. This sign might be looked for in various other conditions and might, perhaps, in course of time become valuable. Care must be taken to distinguish between reflex grimacing and tic.

The Influence of Sea Salt on the Development of the Ova and Larvæ of Ankylostomum.

At a meeting of the Academy of Medicine held on July 25th M. Calmette said that he had found that common salt had no action on the ova of ankylostomum, but that, on the other hand, it affected powerfully the larvæ even in a solution of 2 per cent. strength. In salt water the larvæ generally died from two to seven days after coming out of the ovum. M. Calmette made experiments with the water of four ditches at Valenciennes the water in which contained salt added in proportions varying from 1·16 to 3·97 per cent. In the solutions of 1·16 per cent. strength the ova hatched out quite well but the larvæ died in 15 days. In the solutions of 3·97 per cent. strength the ova did not hatch out, but if after some time they were transferred to a normal medium hatching then took place, which proved that the salt had no destructive action on the ova. Salt water, however, could not be used in coal mines for the prevention of ankylostomiasis and energetic disinfection of the infected areas would be necessary.

Poisoning by Unripe Tomatoes.

A family consisting of four persons—father, mother, and two sons—fell ill two and a half hours after one of their meals, all complaining of violent colic and profuse diarrhœa. The father and one of the sons were in a very low condition and the medical man who was called in was surprised to find dilatation of the pupil in all the patients. The cooking vessels showed no particular feature; meat did not form a part of the food; and the only constituents of it which attracted attention were some tomatoes not fully ripe. The patients soon recovered after taking ipecacuanha and some tea with rum in it. A few days later the same practitioner was called to see a young man who presented similar symptoms one and a half hours after taking food which consisted partly of tomatoes. Some of them remained over and were seen to be not quite ripe. These two cases are interesting, for examples of poisoning by tomatoes have hardly ever been reported.

August 7th.

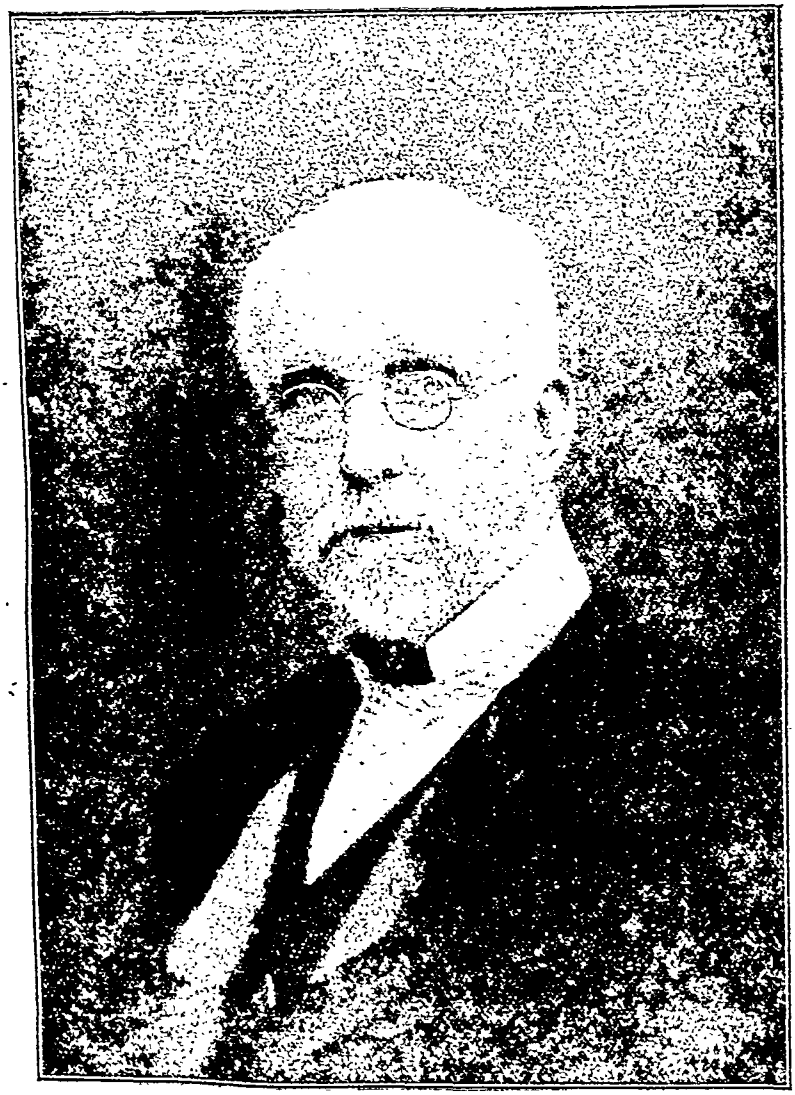
Obituary.

CHRISTOPHER HEATH, F.R.C.S. ENG.,

CONSULTING SURGEON, UNIVERSITY COLLEGE HOSPITAL, ETC.

WE regret to announce the death, which occurred suddenly on August 8th, at his residence, 36, Cavendish-square, W., of Mr. Christopher Heath, F.R.C.S. Eng., Emeritus Professor of Clinical Surgery in University College, London, and a past President of the Royal College of Surgeons of England. Christopher Heath was born in London in 1835, being the grandson of Mr. John Heath, a surgeon in the Royal Navy, who served in the flagship under Lord Howe about 100 years ago. He was educated at King's College School and at King's College and King's College Hospital, London. He served as a surgeon with the Baltic Fleet during the Crimean war in 1855 and in 1856 he became a Member of the Royal College of Surgeons of England, proceeding to the Fellowship in 1860. In the year 1856 he was appointed demonstrator o anatomy at Westminster Hospital and six years later h was made lecturer on anatomy and assistant surgeon at th same hospital. In 1866 he was appointed assistant surgeo and teacher of operative surgery at University Colleg Hospital and in 1875 he became Holme professor o clinical surgery and full surgeon at the same hospital. It was while he was at Westminster Hospital that he wrote his well-known "Practical Anatomy," a ninth edition of which was published in 1902, and the year after his appointment to University College Hospital he was awarded the Jacksonian prize for his essay upon "The Injuries and Diseases of the Jaws, including those of the Antrum, with the Treatment by Operation or Otherwise." In 1881 he was elected a member of the Council of the Royal College of Surgeons of England and in 1895 President of that body, a post which he held also during the year 1896.

Christopher Heath was an admirable teacher and the clearness and practical nature of his style are well known by his clinical lectures on surgical subjects, of which he published two series—one in 1895 and the second in 1902. Among his other well-known works were "A Course of Operative Surgery," the second edition of which appeared in 1884, and the widely-read "Manual of Minor Surgery and Bandaging," which ran into 12 editions. He was the editor of "A Dictionary of Practical Surgery," a well-known work which appeared in 1886. In 1897, as President of the Royal College of Surgeons of England, it fell to his lot to deliver the Hunterian Oration, the text of the oration being "John Hunter considered as a Great Surgeon." A very full abstract of the lecture appeared in THE LANCET of Feb. 20th, 1897, and in the same year he had the honour of delivering the second course of the Lane Medical Lectures which had recently been founded in connexion with the Cooper Medical College in San Francisco. To quote the words of Dr. Cooper Lane, the President of the College, "this course was addressed especially to the students of that school but was also attended by some hundreds of medical men of the Pacific coast; the attention of the audience to the teachings of this eminent English surgeon was markedly



Chrs Heath

intense and reverent. The closing lecture, 'A Century of Surgery,' was replete with illustrations of the advancement of surgery during the nineteenth century. As a contributor to this progress great distinction was given to Lord Lister. Other men, both Europeans and Americans, who have aided in this advancement received appropriate mention. The lectures of Mr. Heath were characterised by a judicious blending of the science and the art of surgery—of the one not so much as to be tedious, of the other enough for guidance to the surgical practitioner. He taught how in boldness not to be rash, how in conservatism not to be inactive. For the appreciated and satisfactory work done by Mr. Heath in San Francisco the New World now brings its honest tribute to add to the honours and renown, so well and worthily won, with which the Old World has so long distinguished him." It was upon this occasion that the University of Montreal conferred upon Mr. Heath the honorary degree of LL.D.

With regard to his surgical work Christopher Heath was a very bold and successful operator and having served as house surgeon to Sir William Fergusson at King's College Hospital he acquired much of the energy and quickness in operating which distinguished that great surgeon. It was in the surgery of the jaw that his operative power could be seen at its best and no one who has seen Mr. Heath removing the superior maxilla is likely to forget the operation. The rapidity and the decision with which it was done were very striking. He was fertile in resources and devised many ingenious methods of overcoming difficulties occurring in the practice of surgery. He had had much operative experience before the introduction of antiseptic surgery, and though he adopted and religiously practised the routine which characterised Listerism at its first introduction yet he was inclined to look down upon many of the precautions as useless fads, and therefore he welcomed the simplifications which more recent years have effected in its procedure. Great, however, as Mr. Heath was as an operator yet it was in his teaching that he shone pre-eminently. For many years as Holme professor of clinical surgery it was his task to instruct and to catechise the students about to present themselves for examination in surgery and the value of these classes to candidates was very great. At one time Mr. Heath had done much "coaching" in surgery and this experience no doubt stood him in good stead; his periods of office as an examiner were also doubtlessly of use, but whatever may be the explanation of it, the fact remains that as a teacher he was truly great. The facts which he communicated to his pupils and the answers which he endeavoured to elicit from them were exactly the facts and the answers which were needed for the *vivâ voce* examinations in surgery. He was somewhat inclined to think that the bacteriological theory of disease was a little overdone and he attached more importance than is customary now to what are called the contributory causes of disease and it must be confessed that he was partly right in this. It was not, however, only in the examinational aspect that his teaching was of value, for it abounded in useful practical points which were likely to remain in the memory of the hearer for long afterwards.

Christopher Heath was a born controversialist of the old-fashioned type—very direct, a hard hitter, and with an intense belief that his opinion was the right one. As in the cases of the late Lord Grimthorpe and the late Sir William Harcourt, his arguments had rather the directness of the bludgeon than the finesse of the rapier.

Mr. Heath was for a long time a leading contributor to THE LANCET and during his Presidency of the Royal College of Surgeons of England he acted as one of the Almoners of THE LANCET Relief Fund.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Moritz Elsner, at Homburg, after a long illness, at the age of 45 years. He was assistant to Professor R. Koch in the Institute for Infectious Diseases in Berlin and published numerous papers on Examination of Water, on Disinfection, the Value of Formaldehyde, &c.—Dr. Paul Schultz of the Berlin Physiological Institute, at the age of 41 years. He edited Munk's "Physiology" and Oestreich's "Compendium" and published numerous researches on the Physiology of Striped Muscles, of Respiration and of the Brain, as well as papers on many other subjects.—Dr. Augustus P. Dudley, Professor of Gynæcology in the New York Post-graduate School.—Dr. Edvard Schönberg, Professor of Midwifery, Gynæcology, and Children's Diseases in the University of Christiania.—Dr. J. L. Chaufleury van Ysselstein, formerly professor in the Amsterdam Medical Faculty, at the age of 86 years.—Dr. Leopold Treitel, a Berlin laryngologist and otologist, whose writings have dealt mainly with deaf-mutism.—Dr. Eduard Lewy, who is looked upon in Vienna as the founder of modern industrial hygiene and who taught this subject in the Vienna Polytechnic.—Dr. Bernhard Honsell, formerly assistant to Professor von Bruns in Tübingen.—Dr. Josef Brettauer of Triest, a well-known ophthalmologist and a voluminous writer.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Medical Men and Legislation.

Dr. Wiley, of the Department of Agriculture, makes a strong plea in favour of more medical men in our national legislature. He states that in the Fifty-seventh Congress there were 319 lawyers, 93 business men, 32 politicians, 12 editors, eight farmers, three teachers, one clergyman, one military man, and three physicians. In view of the great amount of sanitary matter involved in modern legislation it is to be deplored that the medical profession is not largely represented, and by the ablest medical men of the country. It is acknowledged by all that the building of the Panama Canal is more a sanitary than an engineering problem. The men who will really build the canal will be the physicians and health officers who eliminate the germs of malaria and infectious diseases from that locality. If the canal fails it will not be for the lack of dredges, shovels, picks, or machinery nor for want of money, but will be due to the ravages of cholera, of yellow fever, and of other malarial diseases.

The Campaign against Tuberculosis.

The recent meeting of the National Association for the Prevention and Study of Tuberculosis reveals the remarkable progress which has been made within the last year or two in simplifying the methods of prevention and treatment of this disease. The outlook now appears to prove that if equal progress continues to be made the great white plague, the scourge of the race for centuries, will be exterminated from civilised communities within a few years. Climate is now no longer regarded as essential or even the most important factor in its treatment. It is not so much the quality as the quantity of the air consumed. One locality is better than another only because the conditions favour living out of doors. The roof-garden in the city gives as good results as the far-away resorts of Colorado, Arizona, and New Mexico, provided the patient properly and persistently resorts to it. Protests are now being made by the people of the Far West against sending tuberculous persons from comfortable homes in the Eastern States to their climate. An important result of the new opinions in regard to the value of fresh air everywhere in the treatment of tuberculosis is the creation of local sanatoriums in every community for the benefit of the poor. It is no longer a question of State sanatoriums but the agitation is in favour of a sanatorium for every municipality and hamlet. The reports of the association at its late meeting show extraordinary activity among the entire people of this country in adopting the measures recommended for the prevention and treatment of tuberculosis and a greatly diminished death-rate from this disease in the large cities.

Tetanus Neonatorum in Cuba.

The President of the Superior Board of Health of Cuba, Dr. Carlos J. Finlay, attributes the frequency of this disease in that Republic as due to the use of a cheap cotton wick with which the funis is usually tied. An investigation shows that of six balls of this material five were found to be infected with the tetanus bacillus. The mortality records show that in two years 2902 deaths from tetanus were registered. Of this number 2430 occurred in the first year of life. That death was due to infection through the umbilicus was made more certain by a special investigation of 141 deaths by tetanus in the district of Havana, 131 of which occurred in the first year and ten in the second year of life. The remedy which the board has adopted is the distribution of sterile ligature material to the poor throughout the island with information as to the danger of using material of doubtful quality for ligatures. The distribution of sterile ligatures in the city of Havana was followed by a fall of the mortality from this disease from 64 to 38 in 1902 and from 38 to 33 in 1903.

The Conservancy of Potable Waters.

Little attention has hitherto been given to the protection of rivers and lakes in the United States from pollution. But the constantly recurring epidemics in cities and villages, traceable to the infection of the drinking waters, are beginning to excite a much-needed public interest in the subject. The matter was brought to the attention of the International Engineering Congress, when the fact was brought out that 75 per cent. of the 28,000,000 people living in cities discharge their sewage into inland waters, 23 per cent. into the sea or tidal waters, and only 4 per cent. maintain sewage purification plants. Several States have adopted more or less stringent laws against the pollution of running streams and lakes and if the present agitation continues the time is not distant when all urban populations will be compelled to maintain effective disinfecting plants.

New Tax on Immigrants.

The enormous and still increasing number of immigrants to this country is beginning to excite the interest of the public authorities. It is estimated that at least 1,000,000 immigrants will come into the United States during the fiscal year. This number will break all former records. It is learned by agents of the Government who are stationed at the ports of embarkation that foreign governments encourage in various ways the emigration of the criminal classes and those who are likely to be a public charge. This opinion is confirmed by observations made at the great immigration depôts in this country. The result is that the President will recommend to the next congress that the per capita tax on all immigrants be raised to $25 with a view to reduce the number of undesirable immigrants.

Disease due to Electricity.

An interesting observation has been made by Dr. Millener of Buffalo in regard to a disease that has appeared among workers in power-houses. These houses are located at Niagara Falls and 19 cases came under his investigation. It appears that in the case of persons whose employment brings them into the immediate presence of high voltage, alternating current generating or transforming machines, there uniformly result a grave disturbance of the digestive organs, loss of appetite, distress after eating, and whitening of the complexion almost to the colour of chalk. He attributes the cause to the chemical influence of either electric rays or some ray unknown as yet.

July 31st.

NOTES FROM INDIA.

(From our Special Correspondent.)

The Period of Study for Indian Medical Students.

The proposal to increase the period of study for medical students in the Calcutta School from five to six years has been under consideration for some time and was fully discussed at a recent meeting of the University. It was decided, however, to let matters remain as they are. Upon the prospect of an additional year's work a certain section of native medical men, supported by a limited portion of the native press, has been recommending students to go to Japan to study medicine rather than to go to Europe or to remain in Calcutta. One reason given for this advice is the reputed cheapness of study and of living in Japan, while at the same time it is argued that the education is equally good. It is forgotten that students who do not take qualifications recognised by the Government have naturally to shift for themselves as best they can in various forms of private practice. That a certain section of the native press should support such a proposal is not altogether astonishing and it is taken advantage of to attempt a sort of rebuff to British and European medical pretensions. In fact, the proposal was very inadequately considered on its merits and was chiefly made use of as a political move. It is poor patriotism, however, on the part of the Bengali "nation" to sacrifice its medical students for the sake of a very doubtful political snub.

The Plague Epidemic.

The plague epidemic has so far declined that there were only 1742 deaths reported for the week ending July 8th. Of this number the Punjab returned 1112, Bombay Presidency 321, Burma 157, Bengal 61, and the United Provinces 28. The Central Provinces, Central India, and Rajputana are said to be free but this is very doubtful. The great outcry and the disturbances which are raised from time to time about plague are almost invariably about measures and not from fear of the disease. During the past year all the usual religious fairs have been held and the dangers of plague have not diminished the numbers attending them. A warning was issued but there was no prohibition. In the Magh Mela at Allahabad only two cases of plague were reported. In the Dikhanti fair at Hardwar no epidemic disease was discovered and the same is reported of the Dadri fair at Ballia where 750,000 persons attended. It is possible that these fairs being held out of doors rather improve the health of the pilgrims and except for cholera the dangers of disseminating disease are comparatively slight. For the six months of plague in Rangoon there have been 1583 deaths and the expenditure has been Rs. 1,12,285. The disease, however, is still claiming a few victims and several schools have been recently attacked. In Calcutta there have been over 7000 deaths during the same period—not a large proportion compared to its size—and as far as can be gather the expenditure has been very much less. It is reporte that Dr. Martin and the officers engaged in investigati the etiology of plague will remain in India until Octobe They are now engaged in research work in Bombay.

Mortality in the Bombay Presidency.

The report of the sanitary commissioner for the Bomba Presidency for the year 1904 shows an unhealthy state in th province. The deaths exceeded the births by 115,000. I the previous year the deaths were in excess by 234,000, s that the province has decreased in population in two yea by 350.000. It is estimated that since plague first broke ou in 1896 the population has diminished by 1,150,000, and tha as plague deaths have accounted for 1,080,000 there are othe unfavourable causes at work. To those who know ho plague is reported the obvious explanation is that thes deaths have been largely under-estimated. It is noted tha in Ahmedabad the infantile mortality is 550 out of every 100 registered births.

Vaccination in Assam.

Vaccination in Assam seems to be carried on with earnestness and vigour as operations have increased 7 per cent. and one vaccination is performed for every 20·5 persons, whereas the rate in Bengal is 1 to 27. Amongst some of the hill tribes opposition exists to vaccination and in some of the large valleys inoculation is largely practised. The Shillong vaccine depôt is said to have supplied excellent lymph. The percentage of reported successes is put at 98·8. In 11 towns only is vaccination compulsory and it is estimated that in these 71 per cent. of the infants are protected.

July 21st.

Medical News.

Victoria University of Manchester.—At examinations held in the Faculty of Medicine in July the following candidates were successful:—

Final Examination.

Part I.—Daniel Dougal, Philip Ferguson, Jane A. Fleming, C. L. Franklin, E. F. S. Green, J. T. B. Hall, Cecil Hibbert, J. B. Macalpine, R. H. Mercer, F. R. Parakh, G. F. Porter, A. E. Quine, W. H. Ross, H. G. Ward, J. S. Webster, Edgar Wharton, W. A. Wheeldon, A. W. T. Whitworth, and William Wilson.

Part II.—Herbert Ainscow, B. M. Bennett, Frank Boothroyd, T. M. Bride, W. J. Cox, *C. M. Craig, W. R. Douglas, W. B. Hill, Lawrence Kilroe, A. J. Landman, *J. D. Marshall, G. C. Mort, Robert Ollerenshaw, H. B. Pare, Ethel M. Phillips, Joseph Rickards, Leonard Thorp, Douglas Wardleworth, and *S. R. Wilson.

* With honours.

Second Examination.

A. Anatomy and Physiology.—John Allen, Elsie Brown, J. F. Dow, A. K. Eatock, Edward Gandy, J. L. Moir, and H. V. White.

B. Materia Medica and Pharmacy. J. A. Bateman, R. J. Batty, T. B. Bolton, Norman Booth, C. G. Brentnall, C. H. Broomhead, George Crawshaw, W. C. Denniston, H. A. Dunkerley, Frances M. Huxley, F. F. Laidlaw, E. K. Lomas, W. P. Marshall, W. W. Martin, John Morley, Alice Oberdorfer, T. M. Popple, James Ramsbottom, J. B. Rigg, M. C. Skillern-Lawrence, H. E. R. Stephens, John Thompson, R. B. Thompson, W. W. Uttley, and T. G. Williams.

The undermentioned candidates for the degrees of Bachelor of Medicine and Bachelor of Surgery were presented to, and admitted by, the Vice-Chancellor, Dr. A. Hopkinson, on July 27th. The presentations were made by Professor R. B. Wild:—

Colin M'Kean Craig, John Dodds Marshall, and Sidney Rawson Wilson, each second-class honours; Herbert Ainscow, Bertram Marriott Bennett, Frank Boothroyd, Thomas Milnes Bride, William Joseph Cox, William Robert Douglas, William Bertram Hill, Lawrence Kilroe, Abraham Judah Landman, George Cecil Mort, Robert Ollerenshaw, Henry Burton Pare, Ethel Margaret Phillips, Joseph Rickards, Leonard Thorp, and Douglas Wardleworth.

University of Edinburgh.—The following is the official list of passes at the recent professional examinations for degrees in medicine and surgery:—

First Professional Examination.—D. C. Adam, David Aiken, R. J. Allsopp, Fergus Armstrong, T. H. Balfour, G. E. K. Branch (with distinction), J. A. Browne, B.A., O. S. Bullock, J. R Bullman, W. L. Burgess (with distinction), B. N. Burjorjee, G. L. Cawkwell, J. J. P. Charles, A. Dumas Child, W. F. Christie, Gladys H. Cook, James Crocket, J. M. Dalzell, Lucy E. Davies, R. W. Davies, W. N. Davies, Jemima B. Dickie, John K. M. Dickie, Adelaide A. Dreaper, J. W. C. Drever, William Dunlop, A. L. Dykes, J. M Elliot, A. M. Elliott, Euphemia L. Farmer, B A., H. G. Feltham, W. C. Fragoso, F. R. Fraser, Mary M. Gardner, G. H. Garnett, A. W. Gill, V. H. Gordon, W. T. Graham, E. S. B. Hamilton, H. F. Hamilton, Robert Hamilton, R. C. Harkness (with distinction), John Henderson, B. J. O. Saunders, Subrata Chunder Sen, and W. O. Welply.

Foreign University Intelligence.—*Baltimore (Johns Hopkins University)*: Mrs. Florence R. Sabin, M.D., has been appointed Assistant Professor of Anatomy.—*Chicago (Rush Medical College)*: Dr. John B. Murphy of the North-Western University Medical School has been appointed Professor of Surgery.—*Florence*: Dr. E. Filippi has been recognised as *privat-docent* of Experimental Toxicology.—*Greifswald*: Dr. Johannes Sobotta of Wurzburg has been elected to the chair of Anatomy, vacated by the retirement of Dr. Solger.—*Groningen*: Dr. de Vries Reilingh has been recognised as *privat-docent* of Physio-therapeutics.—*Halle*: Dr. Gabriel Anton of Gratz is expected to succeed the late Professor Wernicke in the chair of Psychiatry.—*Innsbruck*: Dr. Bernhard Mayrhofer of Linz has been appointed Extraordinary Professor of Odontology.—*Leipsic*: Dr. Hans Steinert has been recognised as *privat-docent* of Internal Medicine.—*Naples*: Dr. Rosario Buccheri has been recognised as *privat-docent* of the Surgery of Children.—*New York (Post-Graduate School)*: Dr. Samuel W. Bandler has been appointed Assistant Professor of Gynæcology.—*Padua*: Dr. Ettore Ravenna has been recognised as *privat-docent* of Pathological Anatomy.—*Rome*: Dr. Samuele Sereni has been recogised as *privat-docent* of Histology.—*Rostock*: Dr. Hermann Brüning of Leipsic has been recognised as *privat-docent* of Children's Diseases.—*St. Petersburg (Military Medical Academy)*: Dr. A. Redlich has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Strasburg*: Dr. Gustav Schickele has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Tokio*: Dr. Elwin Baelz, who taught medicine in the University for 25 years, most of the present generation of Japanese medical men having been his pupils, has now returned to Stuttgart, his birthplace. He had a great "send off," both by Japanese and by the English residents. The Emperor conferred upon him the Grand Cross of the Rising Sun.—*Turin*: Dr. Filippo Carta has been recognised as *privat-docent* of Surgery.—*Vienna*: Professor Nothnagel's chair has been declined by Professor Friedrich Kraus, Director of the Second Medical Clinic in the Berlin Charité. The selections for the chair of Hygiene, which has now been vacant for three years are: (1) Dr. Arthur Schattenfroh of the Vienna Institute of Hygiene. (2) Professor Prausnitz of Gratz, and (3) Professor Lode of Innsbruck.

A Russian Medical Editor and his Colleagues.—As is known, the editor of the *Journal of the Pirogoff Society of Medical Men* has been cited to answer for the appearance in the journal of articles not allowed by the censor. The provincial medical practitioners of a large number of districts have addressed the Procureur of the Moscow judicial circuit saying that they as contributors to the journal desire to be included in the indictment to show "their solidarity with the editor."

The Water-Supply of Mortehoe and Woollacombe.—The new water-supply for Mortehoe and Woollacombe in Devonshire was inaugurated on August 1st. The new supply is an extension of the Ilfracombe undertaking, being connected to the Ilfracombe mains by four and a half miles of iron pipe. The cost of the scheme is about £7000, exclusive of £2000 which will be required for the filter beds.

High Death-rates in Chili.—Mr. Rowley, acting British Consul-General at Valparaiso, in his report for 1904, just received at the Foreign Office, states that the mortality per 1000 was 55 in Talca, 54 in Chilán, 47 in Concepcion, 46 in Serena, 45 in Valparaiso, 43 in Curicó and Talcahuano, 38 in Santiago, and 35 in Antofagasta.

Sewage Disposal at Tavistock.—A Local Government Board inquiry was held at Tavistock in Devonshire on August 2nd, respecting the application of the urban district council for sanction to borrow £6250 for the purposes of sewerage and sewage disposal.

Teignmouth Hospital.—As a result of a recent fête the sum of £200 has been raised for the Teignmouth Hospital.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Factories and Workshops Legislation.

In the last days of the session an important private Members' Bill was introduced with the object of amending the law relating to factories and workshops It was brought in by Mr. Tennant, Mr. Button, Sir Charles Dilke, Sir John Stirling-Maxwell, Mr. Burns, Mr. Talbot, Mr. McKenna, and Mr. Haldane. The promoters realised, of course, that no progress could be made this year but now that the text has been issued as a Parliamentary paper the public interested will be able to consider the proposals and from the Parliamentary point of view that is helpful. It is pointed out in a memorandum printed with the Bill that the object of the first clause is the improvement and enforcement of the law relating to the sanitary condition of all places to which work is taken by outworkers. It is proposed to treat all such places, unless specially exempted by the Secretary of State, as if they were workshops, so far as concerns the provisions of the Factory Act and the Public Health Acts which relate to sanitation and inspection. It is also proposed to extend to the giver out of work the same responsibility for the sanitary condition of these places as is already placed upon the actual occupier or owner under the existing law Under this scheme the law will be enforced in the first instance, as at present, by the sanitary inspector Thus no new official will be introduced, unless the present official makes default, in which case the factory inspector, by virtue of his supervisory control over workshops, will have power to act The second clause, which also relates to outworkers, is intended to require further precautions with the object of preventing the giving out of clothes to be made, cleaned, or repaired on premises where there is infectious disease The Bill contains several new requirements with regard to the sanitary conditions of factories and workshops, especially with regard to overcrowding in underground workshops, the provision of adequate window space in new factories and workshops, precautions against injury to eyesight by artificial light, the condition of floors, protection against wet, the provision of lavatories, and the supply of drinking water for workpeople At present the provision of adequate ventilation is not compulsory except in special cases and for special purposes, it is proposed to make it compulsory everywhere

HOUSE OF COMMONS.

THURSDAY, AUGUST 3RD

Overcrowding of Wards for the Insane in a Workhouse.

Mr. JOSEPH DEVLIN asked the Chief Secretary for Ireland whether his attention had been called to the overcrowding of the wards for the insane in the Belfast workhouse, due to the fact that the Belfast corporation refused to supply the necessary asylum accommodation for the patients, and whether this overcrowding was denounced by the official inspector of lunacy in December, 1904, who recommended that inexpensive asylum accommodation should be provided for these patients elsewhere, and whether, seeing that in spite of the official recommendation nothing had been done by the corporation in the matter and that the number of these patients at the workhouse was increasing, he would order an inquiry into the subject or cause effective representations to be made to the local authorities with regard to it —Mr. LONG answered The number of insane inmates of Belfast workhouse has in recent years been greatly reduced by the transfer of such persons to the Belfast district lunatic asylum Since 1898 the number of insane in the workhouse has been reduced from 436 to 96 In December, 1904, the inspectors of lunatic asylums recommended that inexpensive buildings should be erected in connexion with the asylum for the accommodation of the insane inmates of the workhouse The necessary buildings are now in course of erection

The Alleged Harsh Treatment of a Medical Officer.

SIR WALTER FOSTER asked the President of the Local Government Board whether he would explain why a district medical officer of the Aylesbury union after being re elected for 23 years in succession had now, when 64 years old and eligible in one year for superannuation, been deprived of his appointment, and whether, in view of the Superannuation Act, 1896, he proposed to take any and if any, what action in the matter —Mr GERALD BALFOUR replied Until recently the late medical officer did not reside in his district and hence he was only appointed from year to year I am not informed why, when an appointment had to be made this year, the guardians preferred to appoint the present holder of the office but it was within their competence to do so if they thought fit The matter is not one in which I can take any action

Small pox in Liverpool

dent of the Local Government
lled to the recently published
of Liverpool upon small pox
the conclusions arrived at by
Dr R J Reece, that small pox
ls, and whether, in view of the
overnment Board proposed to
issue any further report or observations on the subject of the Liverpool small pox hospitals —Mr GERALD BALFOUR replied I have seen the
report of the medical ocal Government Board
proposes shortly to to the Liverpool town
council on the subject

MONDAY, AUGUST 7TH

The Medical Profession and the Army

Dr E C THOMPSON asked the Secretary of State for War what steps had been taken to form a reserve of officers to the Royal Army Medical Corps —Mr ARNOLD FORSTER answered The question of whether it may be possible to form a reserve has been under consideration but no
decisi
Mr whether there was a properly
traine lance of any army exceeding
55,000 Mr ARNOLD FORSTER replied
The w vide for a considerable portion
of the medical staff being civilians As the numbers of the latter available on mobilisation have not been determined on it would not be practicable to give the honourable Member any precise figures on the subject I may add that the Army Council is aware that the strength of the Royal Army Medical Corps is not yet adequate and it is making every endeavour to increase it The experience of the last war showed that we can rely on a large number of highly trained and competent civilian medical officers

TUESDAY, AUGUST 8TH

The Nursing of the Sick Poor in Workhouses

Mr TALBOT asked the President of the Local Government Board whether the order which he had announced to be in preparation with regard to the nursing of the sick poor in workhouses might be expected to be issued before the end of the current year —Mr GERALD BALFOUR replied I hope that this may be done

SEALE.—On July 5th, at Oakfield, Ceres, C.C., the wife of F. A. Seale, M.D., of a daughter.

DEATHS.

HEATH.—On August 8th, at *Cavendish*-square, Christopher Heath, F.R.C.S., aged 70 years.

OGLE.—At the Vicarage, Highgate, on August 8th, John William Ogle, M.D. Oxon., F.R.C.P. Lond., of 9, Gloucester-place, Portman-square, London, consulting physician to St. George's Hospital, aged 81 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

DIFFICULTIES UNDER THE VACCINATION ACTS.

To the Editors of The Lancet.

Sirs,—In your note on the letter from your correspondent "A" you are in error in saying that "the public vaccinator gets no fee unless he actually does vaccinate the child." A minimum fee of 1*s.* is due to him for every name inserted in the "H" forms sent him by the vaccination officer whether he vaccinates or not. As regards your correspondent "A," I advise him to acquaint himself with, and comply with, the Vaccination Acts; he will then increase his fees, will serve his country better, and there will be no excuse for anyone to call at his patients' houses. Thus he will not be worried with exaggerated and often untrue stories about the public vaccinator and, in addition, he will not find it necessary to rush into print to air his ignorance about the above much-maligned individual. Your correspondent is like all the other grumblers, wrong in his law.

I am very tired of the complaints which appear from time to time against public vaccinators and I have come to the conclusion that in nine cases out of ten they are uncalled for. I feel sure if your correspondent would inquire thoroughly into his complaint he would find either that the actions stated were justified, or had been exaggerated, or nothing of the kind happened. He has apparently only one side of the story.

It is very common for parents to lie to a public vaccinator when he makes his statutory call, offering various excuses about their children. These parents do not wish their children vaccinated and so they will lie to their own doctor. Then some private practitioners seem to adopt the "dog in the manger" attitude and say we cannot vaccinate and no one else shall. In other cases when they cannot, or will not, pay for the postponements (if any) and operation and the public vaccinator is the only one who is able to obtain a fee, the private practitioner grudges him it. I inclose some correspondence which shows how some of these complaints turn out when sifted.

I am; Sirs, yours faithfully,

Margate, August 7th, 1905. J. J. Hemming;

*** We are quite aware of provision (*a*) of Article 3, Section 1, and of Section 2 of the same article of the Vaccination Order, 1898, but the minimum fee of 1*s.* is not a fee for visiting.—Ed. L.

A WARNING TO MEDICAL MEN, PRIVATE HOMES, AND INSTITUTIONS FOR MENTAL CASES.

To the Editors of The Lancet.

Sirs,—Medical men and others who carry on homes should be very much on their guard just now for there is going about in the London suburbs a most cunning and clever rogue, who has been, and is now, defrauding a large number of medical men and others by a system of the "confidence trick." He is a thin, undersized, consumptive-looking man, of sad and melancholic aspect, high cheek bones, pointed chin, grey eyes, small brownish moustache, and a dirty ivory complexion. He is dressed in black as though in mourning. His story is that he is looking out for a home for his child of ten who is mentally deficient, his two other children being quite bright. He has recently lost his wife and has just come from India where he holds a good position on the Indian railways. He goes into full details about his child and talks freely about epilepsy, retarded development, and hereditary taint. There is nothing whatever to suggest any suspicion about the man up to this stage. He has been recommended to visit the home by a London specialist for children; he is highly pleased with the place, just the ideal he has been looking for; no money is to be spared for the child's comfort. The terms asked are £200 a year. He leaves the house and will write. A letter comes next morning on stamped addressed paper from a house in a fashionable West-End street saying he has decided to place the child in the home and that he will call early that morning. As he is going out to India in a few days he will pay the year's fees in advance. He presents a cheque for £250; quite a mistake, he intended to write £200; however, it can easily be rectified: the owner of the home can give him a cheque for the £50. He was so nice over it and it all appeared so genuine—the worry of leaving his dear child and going out to India. Several addresses were given of friends in case of the child's illness, &c., and stating the train the nurse would bring the child by, he took his leave. A few hours after, suspicions being aroused, the cheque was taken to London and presented at the bank, where it was pronounced a forgery. A wire was at once sent to the bank to stop payment upon the cheque given for the £50, but it was too late, for although "crossed" it had been cashed by a tradesman. The detective department at Scotland Yard was informed at once and from the account given of the man the officials there state that he has been wanted by them for a long time as a clever rogue and forger. Should any reader happen to receive a call from this gentleman it is to be hoped that he will get him to pay a second call and in the meantime acquaint the authorities at Scotland Yard. The house in the West-End he wrote from is empty and has been a long time.

I am, Sirs, yours faithfully,

August 7th, 1905. Vacuus Viator.

*** If "Vacuus Viator," in addition to crossing his cheque, had marked it "not negotiable" the tradesman would probably refused to cash it; or if he had cashed it he would have do at his own risk and would have rendered himself liable to repa amount. The words "not negotiable" on a cheque are a noti the transferee that he must inquire into the title of his trans and rely on his endorsement, as the transferee of a "not negoti cheque cannot have a better title to it than that which the p from whom he took it had. It is therefore a good rule to cro cheques and to mark them "not negotiable."—Ed. L.

A CURIOUS SUPERSTITION.

To the Editors of The Lancet.

Sirs,—Referring to a letter in your issue of June 3rd, which I just seen, under the above heading I may say that it is a com remark of the old women in rural districts of England to say knowing way, if a man should be under the care of a medical during his wife's pregnancy, "Ah! he is breeding for her," or, " you see, doctor, his wife is breeding," implying that the conditi the woman has some occult influence over the health of the husb If you pursue the inquiry you will find they attribute his illne abstention from connubial intercourse during this interesting t which is an assumption unsupported by trustworthy evidence.

I am, Sirs, yours faithfully,

Faversham, August 7th, 1905. F. Fitzherbert J

CHAULMOOGRA OIL AND SYPHILIS.

To the Editors of The Lancet.

Sirs,—I should be glad if any of your numerous readers can su me with information as to the therapeutic effects, action, principle, of oleum gynocardiæ (chaulmoogra oil), especially with referenc the treatment of syphilis. Thanking you in anticipation,

I am, Sirs, yours faithfully,

Dr. Med. Jos. Fr. von Cripp

Bad-Hall, Oberösterreich (Upper Austria), August 1st, 1905.

THE RED LAMP AND THE BARBER'S POLE.

To the Editors of The Lancet.

Sirs,—For some time past I have puzzled over the origin of red lamp which is placed by some medical practitioners outside t "surgeries" and which at night is often, especially in the subu the only attractive object in the whole road. I have asked one or t medical men about it and they do not seem to know why they us themselves and I feel sure it would interest many of them to know history if some one of your numerous readers would tell it. It seem to me to symbolise blood-letting, but the barber's pole appears have been used with that signification when the barber-surge did that kind of work, for I read that it signified "the which the patient grasped, its spiral decoration in imitation of t bandage, and the basin to catch the blood." I read elsewhere, w regard to the basin, "often with a brass basin at the end of it," and also remember to have read somewhere that the pole symbolised t "poll" or head (derived from the middle Dutch "pol"—head), but do not believe this, as the word "pole" seems to have been derived fr Anglo-Saxon "pal" or Latin "palus," a stake.

I am, Sirs, yours faithfully,

Lucus.

HARD WATER AND RHEUMATOID ARTHRITIS.

To the Editors of The Lancet.

Sirs,—My wife suffers acutely from rheumatoid arthritis in the hi joint and from sciatica. Our water-supply is impregnated with lim Would removal from the district or a supply of soft water material facilitate a cure? Everything tried has failed.

I am, Sirs, yours faithfully,

A. M. Z.

August 8th, 1905.

*** So far as we are aware no connexion between rheumatoid arthrit and the character of the water-supply has been recognised. As t removal from the district, a warm, dry, and equable climate is desideratum.—Ed. L.

BOVININE AS A DRESSING.

To the Editors of The Lancet.

Sirs,—Having read the letter under the above title in your issue o August 5th I think it may be worth while to relate my experience o bovinine as a dressing. In the spring of 1904 I had a patient under m care in hospital who was severely burnt on the back. The patient w a woman who in an epileptic fit fell into the fire and had a burn of th third degree from the occiput to the level of the fifth dorsal spine an from the acromial angle on the left side to the middle of the delto muscle on the right. When she came under my care she had a clean granulating wound of irregular shape about 12 by 20 inches in it greatest diameters. I had just read some accounts of the result obtained in America by treating large granulating wounds wit bovinine and determined to try it. I dressed the wound daily wit bovinine and on three occasions covered different parts of the surfac with Thiersch's grafts, dressing them with the bovinine in the same manner as the granulating surface. The grafts took unusually well and the whole surface was completely healed in a far shorter time than I had expected. When the patient left the hospital the whole area that had been burnt was covered with a soft healthy flexible skin and there was no tendency towards cicatricial contraction or deformity. I heard of the patient some months afterwards and there was still no tendency to contraction or breaking down of the new skin. Since then I have used bovinine in several cases in the treatment of chronic ulcers and think that in all cases it hastened the cure. How exactly the meat extract acts I cannot say but I am inclined to think that it affords a suitable nourishment for the rapidly growing new tissues; certainly in the first case, where I employed skin grafts as well, they took more readily and grew more rapidly than usually. The one thing which appears to be absolutely necessary for the success of this treatment is that the granulating surface should be clean and healthy. I may mention that I did not find the mixture of bovinine with antiseptics (as thymol or iodoform) which are recommended a success.

I am, Sirs, yours faithfully,

Dublin, August 7th, 1905. R. ATKINSON STONEY, M.B. Dub.

◆

Mr. Ceci Revis.—The American quart of 32 ounces was, we believe, referred to but this does not affect the general argument in favour of the production of milk on the rigorously clean lines indicated. The first consideration in regard to milk-supply is surely the public health and not dividends.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1905, which was completed with the issue of June 24th, and the Title-page to the Volume, were given in THE LANCET of July 1st.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1905 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

Notes, Short Comments, and Answers to Correspondents.

DIFFICULTIES UNDER THE VACCINATION ACTS.

To the Editors of The Lancet.

Sirs,—In your note on the letter from your correspondent "A" you are in error in saying that "the public vaccinator gets no fee unless he actually does vaccinate the child." A minimum fee of 1*s* is due to him for every name inserted in the "H" forms sent him by the vaccination officer whether he vaccinates or not. As regards your correspondent "A," I advise him to acquaint himself with, and comply with, the Vaccination Acts, he will then increase his fees, will serve his country better, and there will be no excuse for anyone to call at his patients houses. Thus he will not be worried with exaggerated and often untrue stories about the public vaccinator and, in addition, he will not find it necessary to rush into print to air his ignorance about the above much maligned individual. Your correspondent is like all the other grumblers, wrong in his law.

I am very tired of the complaints which appear from time to time against public vaccinators and I have come to the conclusion that in nine cases out of ten they are uncalled for. I feel sure if your correspondent would inquire thoroughly into his complaint he would find either that the actions stated were justified, or had been exaggerated, or nothing of the kind happened. He has apparently only one side of the story.

It is very common for parents to lie to a public vaccinator when he makes his statutory call, offering various excuses about their children. These parents do not wish their children vaccinated and so they will lie to their own doctor. Then some private practitioners seem to adopt the "dog in the manger" attitude and say we cannot vaccinate and no one else shall. In other cases when they cannot, or will not, pay for the postponements (if any) and operation and the public vaccinator is the only one who is able to obtain a fee, the private practitioner grudges him it. I inclose some correspondence which shows how some of these complaints turn out when sifted.

I am, Sirs, yours faithfully,

The Croonian Lectures
ON
THE CHEMICAL CORRELATION OF THE FUNCTIONS OF THE BODY.

Delivered before the Royal College of Physicians of London on June 20th, 22nd, 27th, and 29th, 1905,

BY ERNEST HENRY STARLING, M.D. LOND., F.R.S.,

FELLOW OF THE COLLEGE; JODRELL PROFESSOR OF PHYSIOLOGY, UNIVERSITY COLLEGE, LONDON.

LECTURE III.[1]

Delivered on June 27th.

THE CHEMICAL REFLEXES OF THE ALIMENTARY TRACT.

MR. PRESIDENT AND GENTLEMEN,—It is not until the food arrives at the stomach that any use is made by the organism of the more primitive chemical method of adjusting the secretion of the digestive juices to the presence of food at various sections of the canal. We have searched in vain for evidence of the production of a secretin in the mouth or its mucous membrane as the result of the taking of food into this cavity which might serve as a stimulus to the salivary glands and the processes in this first part of the alimentary canal are so closely associated with consciousness and volition that one would expect their complete subordination to the central nervous system. In the stomach, however, the researches of Pawlow have already pointed to the possibility of some chemical mechanism being involved in the secretion of gastric juice. This observer has shown that gastric secretion begins even before the entry of food into the stomach as a result either of stimulation of the nerves of taste or even of the mental reproduction of sensations of smell and taste. This immediate secretion is therefore largely psychical and is so designated by Pawlow. The efferent channel of the nervous process is represented by the vagus nerves and Pawlow has shown that division of both vagus nerves absolutely prevents this immediate secretion of gastric juice. There can be no doubt that the psychical secretion is the more important factor in the production of gastric juice in normal circumstances. The dependence of normal digestion in the stomach upon the free play of these nervous influences is shown by the indigestion which is a familiar result of mental disturbance. Gastric secretion has, however, two stages. In the first stage there is the rapid secretion due to this psychical stimulation. Two or three hours after the taking of food into the stomach a second rise in the secretion of juice may be observed and this second rise is apparently dependent not on the taste of the food or mental condition of the animal but on the nature of the stomach contents. Pawlow has shown that this second stage occurs even when both vagus nerves are divided and the possibility is at once suggested that this stage is not due to nervous processes at all, but is determined by some chemical mechanism similar to that which we have studied in the case of the pancreas. Pawlow is apparently of opinion that the secondary secretion is due to local reflexes in the wall of the viscus, but recent experiments by Edkins have shown that it is unnecessary to invoke the aid of any such obscure mechanism.

The stomach consists functionally of two parts—namely, the fundus and the pyloric end. In the fundus of the stomach are found the glands which secrete an acid juice. In the pyloric end the glands are devoid of oxyntic cells and the mucous membrane is much more closely adherent to the subjacent muscular coats. After a full meal the food forms a mass lying in the fundus of the stomach, the pyloric portion being at first quite empty. The movements which occur from 20 to 30 minutes after the taking of food involve only the pyloric half of the stomach, the fundus gradually contracting on its mass of food, so that the portions which are already partially digested are squeezed into the pyloric mill, where thorough admixture of the food with the juices takes place. It seems therefore that such absorption as occurs in the stomach takes place solely at its pyloric end. If, then, there be a gastric secretin we should expect it to be formed in the cells of the pyloric mucous membrane under the influence of the acid or food passing to this end of the stomach from the fundus. Injection therefore of an extract made by treating pyloric mucous membrane with the products of gastric digestion should provoke a secretion of gastric juice. On such lines Edkins made his observations. Extracts of the pyloric mucous membrane were made by rubbing this up with 5 per cent. dextrin, with dextrose or maltose, or with peptone. A dog's stomach which had been previously washed out was filled up with normal salt solution under slight pressure. No absorption of salt solution takes place through the stomach, so that at the end of an hour the salt solution could be recovered unchanged. If, however, the extracts made, as just described, were injected in repeated small doses into the veins of the animal under observation the salt solution removed from the stomach at the end of an hour was found to contain hydrochloric acid as well as pepsine, showing that secretion had been excited in the stomach. Injections of dextrin, maltose, &c., by themselves were without effect, so that the secretory results must be due to the injection of some substance produced in the pyloric cells under the influence of these digestive products. This substance, which Edkins calls gastrin, but which would be better named gastric secretin, is produced only from the pyloric mucous membrane, extracts made by rubbing up digestive products with fundus mucous membrane being without influence on the gastric secretion. Edkins has shown that the substance is not destroyed by boiling, so that it evidently belongs to the same class of bodies as the pancreatic secretin described in my last lecture.

It is an old theory, as propounded by Schiff, that certain constituents of the food have a special influence in promoting the secretion of gastric juice. These substances, among which Schiff placed dextrin, were called by him peptogenous and it seems from Edkins's researches that this term is justified and that our future definition of peptogenous substances will be such bodies as can by their action on the pyloric mucous membrane give rise to the production of gastric secretin.

The movements of the pyloric mill have the effect of squirting into the first part of the duodenum, at intervals of a few minutes, a small quantity of strongly acid chyme containing the products of gastric digestion of the foodstuffs. The pylorus opens to admit the passage of a few cubic centimetres of chyme at a time and then closes and remains closed so long as the contents of the duodenum continue to be acid. As soon as the duodenal contents are neutralised the pylorus opens again and allows the propulsion of a further portion of semi-digested chyme into the duodenum. As we have seen, the effect of this acid chyme is to give rise in the cells of the mucous membrane of the first part of the intestine to secretin which, carried by the blood-vessels to the pancreas, excites a flow of strongly alkaline pancreatic juice. We may take it that ten cubic centimetres of pancreatic juice would suffice to neutralise from 15 to 20 cubic centimetres of the acid chyme. Pancreatic juice, however, although it contains many ferments, is dependent for the full display of its digestive activity on the coöperation of the other juices which are poured into the intestines at the same time—namely, the bile and the succus entericus. Pancreatic juice contains preformed both a fat-splitting ferment and a starch-splitting ferment. The activity of both these ferments is, however, doubled or trebled if bile be simultaneously present. Moreover, the fat-splitting properties of pancreatic juice are of little avail to the organism unless bile salts are also present, which by their solvent power on fatty acids and soaps and by their effect on surface tension can enable the absorption of the products of fat digestion to take place. It is essential, then, that the secretion of bile shall take place at the same time as, and in proportion to, the flow of pancreatic juice. The simultaneous and correlated flow of these two juices is effected by one and the same mechanism. Bayliss and I observed that if a cannula were introduced into the bile duct, the cystic duct having previously been ligatured, intravenous injection of secretin evoked not only the flow of pancreatic juice but also an increased flow of bile. Most extracts of the mucous membrane of the small intestine contain small traces of bile salts which are themselves cholagogue and might, therefore,

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the *return of testimonials*, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements *or* Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and *other* Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31 Rue Bapts, Asnières, Paris.

the food or other substances introduced into the mouth. Thus introduction of sand into a dog's mouth evokes profuse secretion of watery saliva; meat provokes secretion of thick, viscid saliva; bread of thin saliva, chiefly from the parotid gland; and so on. The same results can be evoked by showing the dog these substances—i.e., by the psychic reproduction of previous actual stimulation of peripheral sense organs.

In the stomach the psychic secretion, which is so important in inaugurating the digestion of the food, is apparently unaffected by alterations in diet, any variations which may be caused being sufficiently explained by the different digestibilities and therefore different length of stay of the foodstuffs in the stomach. In the case of the pancreas, however, according to Walther and Vasilieff, there is an accurate adaptation of the composition of the juice to the nature of the food, the dog that has been on a bread diet secreting more amylopsin, while the dog on a proteid diet secretes a larger amount of trypsin or trypsinogen. These results have been controverted by Popielski, according to whom the composition of pancreatic juice is determined solely by the strength of the stimulus which the pancreas receives and further experimental work is still required on the subject. If Walther's contentions are supported it will be interesting to determine whether the adaptation of the pancreatic activity to the nature of the food is nervous in character as imagined by Pawlow or whether the mechanism in this case also is chemical. A very interesting example of adaptation of the pancreatic activity to the nature of the food was described in 1901 by Weinland, who stated that, whereas the pancreatic juice of an ordinary adult dog contains no lactase and is therefore without effect on milk sugar, it is only necessary to feed the dog for some time, a week or more, with milk or with milk sugar in order to determine the appearance of lactase in the pancreatic juice. These experiments of Weinland have been confirmed and amplified more recently in my laboratory by Bainbridge. It is easy to judge of the presence of lactase in pancreatic juice by testing the action of this fluid on solutions of milk sugar and Bainbridge therefore took advantage of this adaptation to determine the mechanism by which it was carried out, and especially to decide the question whether the adaptation is of a nervous or of a chemical nature.

What are the limiting conditions? In the first place the reaction is absolutely specific. Unless the animal is taking lactose in its diet no lactase is ever found in the pancreas or in its secretion. The pancreas of newly born animals, for instance, is quite free from lactase, which, however, makes its appearance two or three days after birth as a result of the milk diet. The production of lactase is not a direct reaction of the pancreas to the presence of lactose in the blood, since subcutaneous or intravenous injection of lactose does not cause the appearance of lactase in the pancreas. The intestinal mucous membrane of all animals, whether on a milk diet or not, contains lactase and has an inverting action on lactose. It might be thought, therefore, that the production of lactase by the pancreas was a reaction to the presence of the products of inversion of lactose in the blood. This was found not to be the case. Subcutaneous injection of galactose for several days was not followed by any appearance of lactase in the pancreas or its juice. Nor was the appearance of lactase due to the increased production of this ferment in the mucous membrane and its escape into the blood. Injection of an extract of mucous membrane rich in lactase, repeated several days in succession, was not followed by any appearance of lactase in the pancreas. Injection of lactose into the duodenum and the subsequent injection of secretin after an interval of one hour were ineffectual in causing the appearance of lactase in the pancreatic juice. For the production of lactase in the pancreas or its juice it is therefore necessary that lactose should act on the intestinal mucous membrane for some time. The reaction is a slow one, like the adaptation in Vasilieff's experiments, and is certainly not due to the stimulation of certain nerve endings in the mucous membrane by the lactose.

Yet it was evident from the results already obtained that lactose must act on the pancreas through the mucous membrane of the intestine. An extract was therefore made from the mucous membrane of the whole small intestine of a milk-fed dog. This was filtered through muslin and about ten cubic centimetres were injected subcutaneously into a biscuit-fed dog once a day for three days. The dog was then anæsthetised, a cannula was placed in its pancreatic duct, and ordinary secretin was injected. A flow of pancreatic juice was obtained and this juice was found to contain lactase. This experiment was performed eight times and in each case the juice obtained from a biscuit-fed dog which had been injected with an extract of the mucous membrane of a milk-fed dog contained lactase.

Here, then, we have some glimpse into the mechanism of the adaptation of the pancreas to the nature of the food. As the result of injection of lactose some substance which we may call *x* is produced in the mucous membrane of the small intestine. This substance is carried by the blood to the pancreas and there slowly gives rise to the formation of lactase, which is turned out in the juice when secretion is excited by the entry of acid chyme into the duodenum. We have no knowledge as yet as to the nature of this substance *x*. All we can say is that it is destroyed at a boiling temperature, since boiled extracts of the mucous membrane of milk-fed dogs do not, when subcutaneously injected, cause the appearance of any lactase in the pancreatic juice of biscuit-fed dogs.

Whether the qualitative adaptation of the juice in respect of its trypsin, amylopsin, and steapsin is carried out in a similar fashion we cannot as yet say. We hope that an investigation of the mechanism of this adaptation, which is now proceeding, may throw light not only on the factors involved but also on the nature of the substance which is formed in the mucous membrane and has this marked effect on the activity of the pancreatic cells. Involving, as it does, two distinct sets of cells this chemical adaptation to lactose is more complex than any yet investigated and shows the intimate relation which must exist between the chemical activities of very different organs of the body.

CONGENITAL HYPERTROPHIC STENOSIS OF THE PYLORUS, WITH AN ACCOUNT OF A CASE SUCCESSFULLY TREATED WITHOUT OPERATION.

BY W. J. HARPER, M.R.C.S. ENG., L.R.C.P. LOND.;
AND
JOHN R. HARPER, M.R.C.S. ENG., L.R.C.P. LOND.,
SURGEON TO THE [illegible] DISPENSARY.

THE following is a clinical history of the case. The child, a male, slightly undersized but apparently normal in other respects, was born after a tedious and instrumental labour on June 20th, 1904. Nothing in his condition occurred during the first three weeks to comment upon; he appeared to thrive and was fed upon cow's milk and water in the ordinary proportions for a child of that age. Vomiting occurred once or twice but never in any way to cause any anxiety. Unfortunately the child was not weighed at birth. About July 14th the child started vomiting some of his meals but not enough for us to think of changing his food. On the 21st, however, he was sick six times in the 24 hours and was then put on to peptonised milk, lime-water, and dill-water in small doses, from two to four drachms every two hours, and was given a simple alkaline mixture. His weight about this time (July 22nd) was 6 pounds 12 ounces. For the next few days vomiting continued more or less frequently—on one day once and on others two or three times. Nothing was detected upon carefully examining the abdomen and we thought him to be suffering from gastritis; his bowels were constipated. Benger's food was added to his diet and was carefully given but was invariably vomited at once, and after three days' trial this was discontinued. By July 28th he had gained two ounces in weight in six days and on this day as he had not been sick at all for several hours his peptonised milk was slightly increased in quantity and he was given a teaspoonful of water every two hours. Constipation was very troublesome and was relieved by oil enemata. The following day, however, sickness commenced again and continued for several days in spite of careful dieting. "Humanised" milk was substituted for peptonised milk, being given every two hours in five-drachm quantities; this, however, was most unsuccessful as he vomited 12 times within a few hours of commencing it. Valentine's meat juice the result of the injection of ordinary extracts of intestinal mucous membrane. The presence of bile salts in our extracts was, however, guarded against, since in our experiments on the influence of secretin on bile we used for the preparation of secretin only mucous membrane which had been previously thoroughly extracted with boiling absolute alcohol and proved by special experiment to contain no trace of bile salts.

Still more important for the full display of the powers of the pancreatic juice is the coöperation of the succus entericus. It was shown in Pawlow's laboratory that the proteolytic effects of pancreatic juice obtained from a pancreatic fistula were enormously increased by the addition of a small trace of intestinal juice and it was concluded that the pancreatic juice contains, besides a small amount of trypsin, a large amount of trypsinogen. This latter 'proferment' has no action on proteids. The succus entericus contains another ferment called by Pawlow enterokinase, which has the power of converting trypsinogen into trypsin. More lately it has been shown by Délézenne, as well as by Bayliss and myself, that normal pancreatic juice as secreted contains no trypsin whatsoever. It has, indeed, a feeble proteolytic ferment which, however, is powerless to digest coagulated proteids or even solid gelatin and only slowly attacks unboiled fibrin or caseinogen. The proteolytic ferment of fresh pancreatic juice is therefore no stronger than the ferments which can be extracted from almost any tissue of the body. In the presence of succus entericus, however, the pancreatic juice speedily develops a proteolytic power more marked than that of any other proteolytic ferment we are acquainted with. It dissolves proteids, whether or not coagulated, and rapidly carries them through the stages of hydration to their end-products of amino-acids, bases, and so on, effecting in this way a thorough destruction of the proteid molecule. Certain French observers, Délézenne, Dastre, and others, have imagined that the interaction of enterokinase and trypsinogen is of the same nature as the interaction between antibody and complement, which is necessary for the destruction of red blood discs by hæmolytic sera. Experiments by Bayliss and myself have shown that this view is untenable and have confirmed Pawlow's original statement that the activating effect of succus entericus on pancreatic juice is due to the presence of a body which acts like a ferment. Our results have been fully confirmed more recently by Hekma in Holland and by Falloise in Belgium.

Enterokinase is active in such minute quantities that the presence of the minutest trace of mucous membrane in a pancreatic juice will suffice to activate the latter. It is important, however, that the activation of the proteolytic ferment should take place as speedily as possible after the entry of pancreatic juice into the intestine, and there must therefore be some means by which a flow of enterokinase containing succus entericus is evoked in direct proportion to the amount of pancreatic juice entering the intestine. That such a mechanism is present and is of a chemical nature there can be little doubt, although some discrepancy still exists between different observers as to the exact nature of the chemical mechanism. We have commenced to study the subject but our experiments are not yet far enough advanced to enable us to decide between the rival views. It is necessary to bear in mind that very considerable differences may exist between the mechanism of secretion of succus entericus in the upper and lower parts of the small intestine. It has long been known that there is a gradual increase in the absorbing powers of the intestine as we proceed from its upper to its lower end, and every worker with intestinal fistulæ has noticed an inverse ratio between the secreting powers of the different parts of this tube, secretion being most abundant in the duodenum and least abundant in the lower parts of the ileum. It is possible, therefore, that the various mechanisms described by different observers are really all involved but that their importance varies according to the part of the canal under investigation. Pawlow, as the result of experiments carried out on dogs with intestinal fistulæ, came to the conclusion that two main factors were involved in the secretion of succus entericus—namely: (1) the mechanical distension of the intestinal canal; and (2) the presence of pancreatic juice. He found that a flow of succus entericus could be more easily evoked by the introduction of a small amount of fresh pancreatic juice into the intestine than by any other means and work by his pupils seems to point to the richness of the juice in enterokinase being proportional to the amount of pancreatic juice introduced into the canal. If these observations be correct they would point to the trypsinogen, or some associated substance in the pancreatic juice, as being itself the chemical stimulant for the glands of the intestinal wall. Whether this chemical irritant acts directly or whether it reaches the follicles of Lieberkühn by way of the blood stream is as yet undetermined. Since it is the trypsinogen which needs the presence of enterokinase it would be natural to assume that this substance itself is the active stimulant of the intestinal glands.

A somewhat different view of the exciting agent for the intestinal secretion has been put forward by Délézenne. This observer, working on dogs with intestinal fistulæ at various regions of the gut, obtained practically no secretion except from the uppermost section—namely, that including the duodenum. He finds that the secretion of what we may call duodenal juice, which must be succus entericus, together with a small amount of the secretion of Brunner's glands, is excited simultaneously with the pancreatic juice and the bile by the injection of secretin into the blood stream. According to this observer, therefore, the secretion of the three coöperating juices in the upper part of the small intestine—namely, bile, pancreatic juice, and succus entericus, containing enterokinase—is brought about by one and the same mechanism—namely, the production of secretin in the intestinal mucous membrane under the influence of the entry of the gastric contents. It is, however, only in the upper part of the gut that the chief rôle of the succus entericus can be regarded as adjuvant to the pancreatic juice and it is only here that the intestinal juice contains any large quantity of enterokinase. Lower down in the gut a secretion of alkaline intestinal juice is still of importance in consequence of its content in (a) sodium carbonate for the neutralisation of the organic acids produced in the changes in foodstuffs; (b) the ferment erepsin which breaks down the products of gastric and pancreatic digestion of proteids, converting albumoses and peptones into the nitrogenous end-products, amino-acids, and nitrogenous bases; and (c) the ferments invertase and maltase which complete the digestion of the carbohydrates of the food. To these two ferments we must, in the case of milk-fed animals, add the ferment lactase, without the coördination of which milk sugar is incapable of undergoing assimilation.

According to Frouin the secretion of succus entericus (apparently in the middle part of the small intestine) can be evoked by the intravenous injection of succus entericus itself or by an extract of the intestinal mucous membrane. It is difficult to see the teleological significance of such a mechanism unless we assume that some constituent of the succus entericus, produced by the mechanical stimulation of the foodstuffs themselves, is absorbed into the blood and provokes the secretion of more intestinal juice lower down in the canal in preparation for the reception of the advancing mass of food.

We see then that from the entry of the food into the stomach until its passage through the ileo-cæcal valve there is a continuous chain of chemical reflexes and that the process in any section of the alimentary canal calls forth the activity of the digestive apparatus in the immediately following section. In the stomach this chemical mechanism or reflex is associated with, and probably subordinated to, a nervous reflex mechanism. In the rest of the alimentary canal the chemical mechanism seems sufficient to account for the secretion of all the digestive juices which are demanded by the food. Whether there is in addition a chain of nervous processes the evidence at present before us is not sufficient to decide, though we ourselves have been unable to obtain any satisfactory evidence of their existence. The mechanisms I have described suffice to explain in large measure the adaptation of the digestive processes to variations in the quality of the food supplied. As a rule the more indigestible the foodstuff the longer will it remain in the stomach; the greater, therefore, will be the secretion of acid gastric juice, which is the stimulus which sets free the chain of processes below the pyloric sphincter. Increased secretion of gastric juice will therefore be attended automatically with increased secretion of the other digestive juices.

There is, however, evidence of a more specific adaptation of certain of the digestive juices to the nature of the foodstuffs. Experiments carried out in Pawlow's laboratory have shown that the saliva poured into the mouth varies in consistence and other qualities according to the nature of

in small doses, white of egg, peptonised milk and hot water were all tried but were immediately returned. His condition by now, August 5th, was very grave; his pulse was 140, his temperature was subnormal, his skin was dried up and shrivelled, his extremities were cold and bluish, and the child was wasted to an extreme degree. The tongue was very dry and brown and the bowels were very constipated. He was much too ill to be taken out of his cot and was kept wrapped up in cotton wool. The vomit was always devoid of bile, containing curdled milk and mucus; at times it was intensely acid and sour smelling. Vomiting followed practically immediately the introduction of anything into the mouth—at times being forced out on to the bed as if from a pump. It was never large in amount, unless perhaps it had ceased for a few hours, when everything came up that he had previously taken.

On carefully examining his abdomen the stomach appeared to be dilated and traversing it from left to right distinct waves of peristalsis could be made out following one another in rapid succession at regular and distinct intervals. These seemed to be excited by the introduction of anything into the stomach and often started at once when the abdominal wall was exposed to the air. Sometimes they could only be obtained by palpating the abdomen or flicking it slightly with the finger. They could also be felt when the hand was laid upon the stomach moving across the abdomen. We were fortunate to obtain a photograph (Fig. 1) which distinctly shows this characteristic symptom. On rare occasions we saw a retrogressive wave which evidently started from the pylorus and travelled towards the cardiac end of the stomach; it was noted that it was often accompanied by vomiting. Any food that he was given was in very small quantity—from one to two drachms—and at intervals of from one and a half to two hours day and night. On August 5th he had seven or eight tonic convulsions. On the following day he had 22 and was in a state of extreme collapse, taking no nourishment by the mouth. The pulse was 118. On the 7th and 8th the convulsions were very frequent—from 22 to 24 in the 24 hours. He was now so ill that beyond keeping him warm with hot-water bottles and a teaspoonful of hot water at frequent intervals we did nothing for him. The temperature was 97° and the pulse had fallen to 67. During the next few days, as the convulsions had diminished much in frequency and severity, we again tried him upon peptonised milk and white of egg. Vomiting, however, started at once and on August 10th we commenced to give him injections of normal saline solution, about half a pint twice daily and at first doing nothing else; he retained them and was much less restless, having no convulsions and only a little sickness. By the 14th he appeared to have rallied somewhat, but was still sick three, four, and nine times during the 24 hours. He was now taking peptonised milk and water and occasionally a few drops of Valentine's meat juice and white of egg, a portion of which he certainly retained. His weight on this date was 5 pounds 12 ounces, being a loss of 1 pound 2 ounces in 14 days. He still retained the saline injections, the constipation having to be relieved by an oil or simple enema. He was taking no medicine. On August 18th his weight had further fallen, being 5 pounds 10½ ounces. The temperature was subnormal, the pulse varying from 82 to 64 during the 24 hours; there had been no further convulsions

the latter part of October he had an attack of c
which yielded in a few days to simple treat

By Dec. 25th his weight was 12 pounds. He was taking now only Benger's food with a little barley water. His abdomen had much altered; the peristalsis was present only upon flicking the abdomen. There was rarely any vomiting but still obstinate constipation. On March 30th, 1905, nothing abnormal on examination could be detected. His weight was 18 pounds. On July 1st the child was as in Fig. 2, weighing 26¼ pounds and being about 12 months old. He certainly appeared to have an unusual amount of adipose tissue for a child of his age and the upper part of his abdomen looked unduly prominent. Nothing abnormal, however, could be detected. His health is excellent and his appetite is good. He never has any vomiting and has cut several teeth. Constipation, however, still remains a difficulty.

By far the majority of papers and cases that have been published concerning successful cases of congenital hypertrophic stenosis of the pylorus have been written with the idea of showing the advantages of early operative interference, notably the papers by Wachenheim,[1] Cautley and Dent,[2] Nicoll,[3] Thomson,[4] Stiles,[5] and others. It has occurred to us that the somewhat detailed account of the history of the above case might prove sufficiently interesting for publication in that the child's recovery was entirely due to careful nursing and dieting. The infant, who is the son of one of us, had the advantage of being continuously under medical observation and during the whole of his illness was under the care of his mother and an exceptionally capable trained nurse, to both of whom the credit of the child's recovery is due. The question of operative interference was frequently discussed during the earlier stages of the child's condition but was abandoned owing to his apparently hopeless condition. We had noticed, too, as the child improved, that two cases had been carefully reported by Batten[6] and Gardner[7] in which recovery took place after careful dieting, the patient in the former case, however, unfortunately dying later from an attack of bronchopneumonia. Recoveries have also been reported as having taken place without operation by Ashby,[8] G. F. Still,[9] and J. F. Goodhart.[10]

Etiology.—The causation of this condition is still unertain. The chief theories are the following: 1. That the ondition is due to a primary hyperplasia of the muscular issue at the pyloric end of the stomach, an overgrowth due o an error in development (Dent and Cautley[11]). 2. That he hypertrophy is secondary and results from over-exertion f the muscle, this being due to functional disturbance of the ervous mechanism of the stomach and pylorus (Thomson,[12] shby,[13] G. F. Still,[14] and others). 3. That it seems asonable to combine the above views so far as to believe hat there is some congenital hyperplasia of the pyloric hincter, and that spasm supervenes on this, and is largely sponsible for the symptoms manifested (Rolleston and rofton-Atkins[15]).

Symptoms.—The period after birth at which vomiting, the st symptom, commences varies much—the average is pparently from two to three weeks. In an interesting ble compiled by Wachenheim[16] of notes of 35 cases, in ven vomiting started at birth and in the others from three ys up to six weeks. In de Bruyn Kop's case vomiting rted at birth and the child died at seven weeks with asarca and fluid in the abdomen.[17] In Rolleston and ofton-Atkins's case vomiting and convulsions started 14 ys after birth and death occurred seven weeks after.[18] he vomiting appears to commence at first once or twice a y and to begin with gives rise to no anxiety, until it is nd that treatment and alteration in diet are ineffectual in checking it. There seems to be no difference as to whether the child is brought up on the breast or is hand-fed. When fully developed the vomiting occurs after every meal, which is often ejected from the mouth as if pumped up. The act does not appear to be associated with any pain. The vomitus is usually acid; free hydrochloric acid has been found in a few cases and in the majority of cases bile has been absent. In our case mucus, curdled milk, and sometimes a little blood were found. Where there is much dilatation of the stomach the vomitus has a frothy appearance (Still[19]). Convulsions associated with the vomiting are the result of the absorption of toxic material from the stomach. We noticed that the convulsions shortly ceased after we stopped food by the mouth; it was rarely that any retching was noted. The child's tongue and mouth became dry and parched.

Constipation is a very troublesome symptom; in several cases it alternates with diarrhœa (Wachenheim) and occasionally blood has been found in the stools.

Marasmus.—This is usually progressive: the child rapidly wastes, the skin becomes yellowish-brown, and the tissues dry up and shrivel. In our case the weight fell from 6 pounds 14 ounces to 5 pounds 12 ounces in less than 14 days.

Visible peristalsis and dilatation of the stomach.—This varies very much; in some cases it is not detected at all. When present it is a most characteristic symptom which seems at one time to be excited by simply exposing the abdominal wall in lifting the nightgown, at another by the introduction of food into the stomach or by palpating the abdomen or flicking it with a finger. In our case when it was most distinct, at the time we photographed the child, it was easily elicited by exposure of the abdomen alone; later, as the child's condition improved it could only be obtained by applying a stimulus to the abdominal wall; soon it was often not obtained then, and finally disappeared shortly after the vomiting ceased. Occasionally a peristaltic wave has been noticed returning from the pylorus to the cardiac end of the stomach and usually followed by vomiting.

Palpable tumour in the region of the pylorus.—This is not by any means always detected. It is sometimes not possible to detect the tumour more than two or three times during the illness. Still considers that its "palpability depends on the temporary condition of the muscle at the pyloric end of the stomach and, like an intussusception, it may be felt only when there is some contraction of the muscular coat occurring."[20] It is usually not recognised until after several weeks of vomiting. J. Thomson[21] noticed it as early as the twenty-third day after birth. The temperature is usually subnormal and the urine much diminished.

Treatment.—That a certain proportion of cases of congenital stenosis have recovered without any operative interference is now a generally held opinion but there is no doubt that the majority of observers are strongly in favour of the necessity of early surgical treatment. Cautley and Dent in their exhaustive paper state "that the subjects of the affection under consideration if untreated die at about the third or fourth month," and Wachenheim "considers it an error to continue medical treatment beyond two weeks unless there are very distinct signs of improvement; further than this, all treatment must be surgical as affording the only chance of life, and that not a brilliant one." It is interesting to note the method of treatment adopted in the two successful cases which were not operated upon and of which detailed accounts have been published by Gardner and Batten,[22] the child in the former case being fed upon a teaspoonful of whey every 20 minutes, with later the addition of a little malt and meat juice. In Dr. Batten's case nasal feeding, cow's milk and water (2 to 1) thre ounces every two and a half hours, was the treatment.

In the treatment of our patient we found, after trying cow's milk, Allen and Hanburys and Benger's food, a wet nurse, and "humanised" milk, all unsuccessfully, that we had the best results from small quantities of peptonised milk at very frequent intervals, together with injections of normal saline solution half a pint twice daily. The latter method of treatment we found of the greatest service in counteracting the great drain upon the tissues the result of the excessive vomiting. We preferred this method to that of nasal feeding as the child was so exhausted. In any future case we might be called upon to treat we should certainly wash the stomach

On carefully examining his abdomen the stomach appeared to be dilated and traversing it from left to right distinct waves of peristalsis could be made out following one another in rapid succession at regular and distinct intervals. These seemed to be excited by the introduction of anything into the stomach and often started at once when the abdominal wall was exposed to the air. Sometimes they could only be obtained by palpating the abdomen or flicking it slightly with the finger. They could also be felt when the hand was laid upon the stomach moving across the abdomen. We were fortunate to obtain a photograph (Fig. 1) which distinctly shows this characteristic symptom. On rare occasions we saw a retrogressive wave which evidently started from the pylorus and travelled towards the cardiac end of the stomach; it was noted that it was often accompanied by vomiting. Any food that he was given was in very small quantity—from one to two drachms—and at intervals of from one and a half to two hours day and night. On August 5th he had seven or eight tonic convulsions. On the following day he had 22 and was in a state of extreme collapse, taking no nourishment by the mouth. The pulse was 118. On the 7th and 8th the convulsions were very frequent—from 22 to 24 in the 24 hours. He was now so ill that beyond keeping him warm with hot-water bottles and a teaspoonful of hot water at frequent intervals we did nothing for him. The temperature was 97° and the pulse had fallen to 67. During the next few days, as the convulsions had diminished much in frequency and severity, we again tried him upon peptonised milk and white of egg. Vomiting, however, started at once and on August 10th we commenced to give him injections of normal saline solution, about half a pint twice daily and at first doing nothing else; he retained them and was much less restless, having no convulsions and only a little sickness. By the 14th he appeared to have rallied somewhat, but was still sick three, four, and nine times during the 24 hours. He was now taking peptonised milk and water and occasionally a few drops of Valentine's meat juice and white of egg, a portion of which he certainly retained. His weight on this date was 5 pounds 12 ounces, being a loss of 1 pound 2 ounces in 14 days. He still retained the saline injections, the constipation having to be relieved by an oil or simple enema. He was taking no medicine. On August 18th his weight had further fallen, being 5 pounds 10½ ounces. The temperature was subnormal, the pulse varying from 82 to 64 during the 24 hours; there had been no further convulsions but the vomiting was as bad as ever, starting immediatel anything was introduced into the stomach and occurring as often as seven, nine, 17, and 20 times during the 24 hours. At this time his local condition was much as before but we were able upon two or three occasions to define a small rounded swelling situated to the right of the umbilicus under the costal margins of about the size of a small walnut. Often, however, we were unsuccessful in demonstrating it. A wet nurse was obtained and the child was fed by means of a spoon with her milk but this was a complete failure. The weight now (August 24th) was 5 pounds 8 ounces, the temperature was subnormal, the pulse was 62, and the child looking as if he were about to die at any moment, more shrivelled up and emaciated than ever. He retained the saline injections and nothing else. We had tried a nutrient enema of peptonised milk on several occasions but it had started diarrhœa and was retained for a very short time only. We finally gave up everything except teaspoonfuls of hot water and the normal saline injections and the child remained thus for a day or two when we again commenced teaspoonfuls of peptonised milk and water, which in spite of vomiting two or three times in the day was partly retained. He seemed now, if anything, brighter and upon being weighed we found that he had gained three and three-quarter ounces in three days. The nurse on August 30th started massaging the abdomen twice daily with cod liver oil, particular attention being paid to massage of the stomach wall towards the pylorus. On Sept. 2nd he had not been sick for two days and weighed 5 pounds 13¼ ounces. He was still taking only small quantities of peptonised milk and water and upon again trying nutrient enemata we found that with a little difficulty they were retained. We gave nothing but peptonised milk and continued this treatment for ten days during which he commenced decidedly to improve, his weight being 6 pounds 2 ounces, and except for some slight œdema of his feet and over one eye he certainly looked better. On Sept. 12th we had to stop the nutrient enemata owing to the local irritation they caused but we were enabled still to continue the normal saline injections which, together with an increased amount of peptonised milk by the mouth, given at more frequent intervals than two hours, was the treatment for the next four weeks. The local condition had not altered much. Possibly the peristalsis was not so distinct. We certainly were unable to feel the pyloric tumour that we had previously noticed. It was now unusual for him to be sick more than once a day. On several days there was no vomiting. Abdominal massage with cod-liver oil was still continued. On Oct. 1st his weight was 6 pounds 3¼ ounces. On Oct. 5th Dr. Eustace Smith, in an interview with one of us, recommended the addition of a few grains of pulv. papain compositus to each meal which now consisted of peptonised milk and Benger's food. This was practically the treatment for the next three months. His weight gradually increased and the child began to look much fatter. The only difficulty was that of constipation which was as bad as ever, being only relieved by the oil enemata. The injections of normal saline solution were discontinued on Nov. 27th when the weight was 9 pounds 8 ounces and the child's age was just five months. During the latter part of October he had an attack of enteritis which yielded in a few days to simple treatment.

K C M G Prof W J Simpson Miss S Commissariat, L R C S I H G Waters out twice daily as a routine measure. Had we done this we should no doubt have avoided the convulsions which were at one time so frequent and so severe and were evidently the result of the absorption of toxic material from a dilated stomach. Abdominal massage with cod-liver oil was resorted to in despair but from the progress of the case we cannot help thinking that a certain amount is absorbed through the skin and that a certain proportion of the success of the treatment is due to the oil so absorbed.

SUBDIAPHRAGMATIC TRANSPERITONEAL MASSAGE OF THE HEART AS A MEANS OF RESUSCITATION.

BY H. M. W. GRAY, M.B. ABERD., F.R.C.S. EDIN.,
SURGEON TO THE ABERDEEN ROYAL INFIRMARY.

A FEMALE patient, aged 55 years, was admitted to hospital at 11.45 A.M. on Feb. 23rd, 1905, suffering from marked laryngeal obstruction. She had travelled nearly 30 miles by carriage and train, accompanied by her medical attendant. He was surprised that she had borne the journey so well considering that she had been suffering for about three months previously from increasing dyspnœa which became very urgent at times when the patient was excited. For the past three or four days this had been severe, compelling her to acquiesce in removal to hospital. On arrival she was deeply cyanosed, inspiration was much obstructed and accompanied by a very harsh "baa-ing" noise, and expiration was also interfered with. She was quite conscious and able to reply to questions, though with difficulty. No intralaryngeal examination was made. It was thought that the dyspnœa would subside with rest in bed and orders were given to prepare for tracheotomy immediately after 1 P.M., at which time I should have finished with a clinical lecture in the neighbouring ward. At 12.53 I was told that the patient was dying. On the way to the women's ward a nurse met me saying that she was dead. On entering the ward I heard her make a feeble choky inspiratory effort. Her face was very deeply cyanosed, the large veins standing out on her face and neck. This, however, disappeared with striking rapidity. High tracheotomy was performed at once, with a penknife and the lips of the tracheal wound were retracted with bent hairpins. Very little bleeding occurred from a small vein at the lower end of the wound in the neck. Artificial respiration was immediately proceeded with but only four or five spontaneous breaths were taken by the patient. There was no pulse at the wrist or cardiac impulse from the first. No cardiac sounds could be heard on auscultation. She was pallid, all reflexes had disappeared, the pupils were widely dilated, the muscles became absolutely flaccid, her lips were pale, and her eyes rapidly assumed a "glassy" look. Various methods of resuscitation, including attempted external massage of the heart, were carried out but all to no purpose.

Four or five minutes after the tracheotomy was done the abdomen was opened in the middle line immediately under the xiphoid cartilage, again with my penknife. There was no bleeding. Inserting two fingers I could easily palpate the outline of the heart between the diaphragm and the ribs in front. It was absolutely flaccid. Massage by intermittent pressure was carried out for about four minutes. The compressions were performed about the rate of 70 to 90 per minute. At the end of every 15 to 30 seconds I abated the movements in order to feel any change in the condition of the heart. At the end of the above period I felt the heart becoming firm gradually. After remaining thus for a few seconds a slight tremor was felt. Then very slowly (from 30 to 40 to the minute) the heart began to beat. The pulsations were at first very feeble. I massaged the heart for a few seconds more and then it beat gradually more strongly and quickly until at seven minutes past one it was beating at the rate of about 90, and more vigorously than since admission. The gradual return of the heart's action was indicated to those around by keeping time with my left hand, the other being used for massage. The colour was observed to return to the face and lips, the eyes lost their "glassy" stare, the pupils contracted, and pulsation of the carotids became very visible. During all this time artificial respiration had been kept up by compressing the chest. Very soon after the heart began to beat the patient took a rather deep spontaneous breath and from ten to 15 seconds later another, till by degrees respiration became normal though somewhat frequent. Slight hæmorrhage occurred from the abdominal wound which was then partially sutured and a gauze drain was inserted under the diaphragm. When I left the hospital an hour later the pulse was rather weaker and quicker but still wonderfully good, so that I was rather surprised to hear from the house surgeon that the patient died at 3 P.M., having never regained consciousness. The cause of the laryngeal obstruction was found to be a fairly large cancerous growth. Probably at least ten minutes elapsed between the times when the heart stopped beating and when it began again. Crile records the case of a man whose heart stopped for nine minutes and by the combined effect of artificial respiration, infusion of adrenalin, and manual compression of the heart the cardiac action was restored for 31 minutes.

In December, 1902, I had a similar, though not so striking, experience. I was then removing an ovarian cystoma from a woman, aged 60 years. The pedicle of the growth had just been severed when suddenly the patient became pallid, respiration ceased, and it was found that the heart had stopped. As artificial respiration produced no effect I thrust my hand up through the abdomen and found the heart in a similar condition to that in the foregoing case. In this case, however, only two or three squeezes were necessary to set the heart going again and the patient made an uneventful recovery.

Aberdeen.

A PRELIMINARY NOTE ON

THE PRESENCE OF PIGMENT CONTAINING IRON IN THE THYROID GLAND.[1]

BY G. LOVELL GULLAND, M.A., B.SC., M.D. EDIN.,
F.R.C.P. EDIN.,
ASSISTANT PHYSICIAN TO THE ROYAL INFIRMARY AND PHYSICIAN TO THE CHALMERS AND ROYAL VICTORIA HOSPITALS, EDINBURGH;

AND

ALEXANDER GOODALL, M.D. EDIN., F.R.C.P. EDIN.,
CLINICAL TUTOR, ROYAL INFIRMARY; SENIOR DEMONSTRATOR OF PHYSIOLOGY, SCHOOL OF MEDICINE, EDINBURGH.

(From the Laboratory of the Royal College of Physicians, Edinburgh.)

IN the course of a histological study of the blood diseases we have on several occasions noticed the presence of pigment giving the free iron reaction in the thyroid. Unfortunately the thyroid had not been preserved in many instances, but we now propose (1) to describe the appearances in six cases; and (2) to give an account of the pigmentary changes in the thyroid gland of animals after blood destruction by hæmolytic agents.

Methods.—The gland tissue was fixed in sublimated formalin and sections were stained with eosin and methylene blue to show the general structure. To demonstrate iron we placed sections in a mixture of potassium ferrocyanide and hydrochloric acid and afterwards counter-stained them with carm-alum. In carrying out the latter method we were careful to avoid the use of metal instruments and to use glass vessels only.

1. CASE 1. *Pernicious anæmia with marked pigmentary changes in the organs.*—Each of a series of sections of the thyroid gland showed an area of about the size of a pin's head where there was a marked iron reaction. This was found to consist of a group of thyroid cells, most of which were packed with a yellow coloured pigment and were enlarged to about 20 times their normal size. Many of the neighbouring acini showed no pigmentation but here and there throughout the sections were large, irregularly shaped cells full of pigment lying in the fibrous tissue between the acini. All the pigment gave the free iron reaction.

CASE 2. *Pernicious anæmia.*—The thyroid had undergone some cystic enlargement. There were no areas showing pigmentation but there were a few connective tissue cells between the acini and a few isolated cells lying free in the acini which were packed with a golden-brown pigment giving the iron reaction.

---

[1] Grants towards the expenses of this research were received from the Carnegie Trust and the Mason Fund of the laboratory.

CASE 3. *Severe secondary anæmia following gastric carcinoma.*—In this case there were small pigmented areas scattered at fairly wide intervals throughout the right and left lobes. No pigmentation was found in the isthmus. In the connective tissue between the acini were scattered groups of five or six cells, globular in shape, packed with granules of iron pigment which in many cases obscured the nucleus. Around these groups were other cells containing only two or three small rounded masses of iron pigment. In many of the acini the epithelium lining the vesicles contained a large amount of yellow pigment, especially towards the unattached border of the cells. In the colloid material in several acini were large granular masses like large degenerated cells. Some of the granules gave the iron reaction; others remained golden brown. The colloid material in a few of the acini gave a slight diffuse iron reaction. The pigment in the epithelium of the acini was always more abundant in the case of the smaller vesicles and in this position a smaller proportion of the pigment gave the iron reaction than in the other situations. It was noticed that the colloid material in these small vesicles stained a red colour with eosin and methylene blue, while the colloid in the large vesicles not showing iron was stained blue.

CASE 4. *Medullary leucocythæmia.*—In a small area there was a mass of cellular tissue consisting of ordinary thyroid cells and numerous cells of large size containing iron pigment. Almost throughout the whole gland the interacinous fibrous tissue showed large, irregularly shaped cells full of pigment which gave a brilliant iron reaction.

CASE 5. *Lymphatic leukæmia.*—There were no aggregations of pigmented cells but in epithelial cells lining the acini and in connective tissue cells in the septa throughout the gland were granules of pigment giving the iron reaction.

CASE 6. *Lymphatic leukæmia.*—Iron pigment was found in groups of five or six thyroid cells, in the interacinous connective tissue, and in cells lying free in the acini between the epithelium and the colloid material and sometimes among the colloid.

As yet our collection of "check" material is not large, but we have failed to find the pigment in three cases of lymphatic leukæmia and in a case of death due to injury.

2. *The thyroid in experimental hæmatolysis.*—In this part of the work we were able to utilise material which was obtained in the course of a research by one of us, in collaboration with Dr. D. Noel Paton, on the relationship of the spleen to hæmatolysis. Animals had been injected with a 1 in 50 solution of phenylhydrazin in doses corresponding to three cubic centimetres for each 2000 grammes of body weight. In animals killed a week after the injection we found a marked iron reaction in the thyroid gland. For the most part, however, this reaction was due to a deposition of pigment along the fibrils of connective tissue in the capsule and septa in common with a similar deposition in fibrous tissue in the spleen, lymph glands, &c., as has been described by Heinz[2] and Noel Paton and Goodall.[3] In rabbits and cats we were unable to find any further pigmentary change. In guinea-pigs in addition to the pigmentation along the fibrils of connective tissue there was pigment in large cells lying among the colloid material. In these cells only part of the pigment gave the iron reaction. In one case sections of the parathyroid showed diffuse iron pigmentation of the connective tissue, while the cells were free from pigment. We have examined a very large number of sections of thyroid from all the common laboratory animals in a normal condition and have failed to find pigmentation. It would therefore appear that the condition is associated with an undue vulnerability of the red blood corpuscles. We would note that while iron-containing pigment has been found in the blood conditions and blood destructions described in other organs—as in the liver, the spleen, the kidney, the marrow, and hæmolymph glands—we have been unable to find any notice of its appearance in the thyroid gland. Its occurrence there is of great theoretical and possibly of practical interest.

At the present stage our findings may be summarised as follows:—1. In cases of the diseases of the blood and in animals injected with phenylhydrazin we have found pigment in the thyroid gland. The greater part of this pigment gives the free iron reaction. 2. The pigment is most commonly found in connective tissue cells between the vesicles. It is also present in small scattered areas in the epithelium lining the vesicles and may be found in cells lying free among the colloid material. 3. It is most abundant in the more cellular parts of the thyroid where the colloid vesicles are small.

A CASE OF MIXED-CELL LEUKÆMIA, WITH A SHORT ACCOUNT OF RECENT VIEWS ON ATYPICAL LEUKÆMIAS.

BY CARL HAMILTON BROWNING, M.B., CH.B. GLASG.,
CARNEGIE RESEARCH FELLOW.

(From the Pathological Institute of the University of Glasgow, the Western Infirmary, Glasgow.)

THE following presents a short abstract of the principal points in the clinical history of the case. The patient, a man, aged 57 years, was admitted into the Western Infirmary, Glasgow, in May, 1904, and was under the care of Dr. J. Finlayson, to whom I am indebted for permission to record the case. He complained of pain and loss of power in the legs of three weeks' duration. For about six months previously, however, he had been in failing health and had complained of sweating and palpitation. By occupation he was a stevedore but had given up this work two years before, not on account of his health, however, although his weight had been decreasing for some years. He had been addicted to alcohol but had never been abroad. There was nothing of note in his family history. On examination the spleen was found greatly to be enlarged, measuring seven and a half inches vertically in the left mid-axillary line and extending forward as far as the umbilicus. The hepatic dulness measured five and three-quarter inches in the right vertical nipple-line. No enlarged glands could be made out on palpation. The lung note was clear throughout. The pulse was rapid and there was a ventricular systolic (mitral) murmur. The evening temperature rose as high as 101·6° F. Neither sugar nor albumin was present in the urine. There was no dropsy or ascites.

During his stay in hospital the patient complained principally of great pain in the thighs and knees. The superficial veins of both legs were varicose and there had been an ulcer on the right one for 30 years; but the pain seemed more severe than could be attributed to this cause (possibly due to bone absorption). Three weeks after admission there was epistaxis on two occasions; the second time it was found necessary to plug the posterior nares. Within a week after the epistaxis the patient died, having in the meantime left the hospital, so that a post-mortem examination was unfortunately not secured.

The blood was examined by me about three weeks before the patient's death. The details are as follows:—Red corpuscles, 2,480,000 per cubic millimetre; hæmoglobin, 37 per cent.; leucocytes, 98,300 per cubic millimetre. The following is a differential count of leucocytes[1] (700 cells in a heat-fixed film stained with Ehrlich's triacid fluid):—Neutrophiles, 50·8 per cent. (polymorphonuclears, 38 per cent., myelocytes and transitionals, 12·8 per cent.); eosinophiles, mostly mononuclear, 4·5 per cent.; large hyalines, 40·7 per cent.; small hyalines, 4 per cent.; mast cells, less than 0·2 per cent.; normoblasts, 17 in the course of 1450 leucocytes. The striking feature in this case is, of course, the occurrence of such a considerable proportion of large non-granular cells in a blood picture which is in other respects characteristic of a myelogenic leukæmia.

The large hyaline cells vary somewhat in size but the great majority have a diameter about one and a half times that of an ordinary polymorphonuclear leucocyte. Their protoplasm is non-granular and in heat-fixed films stained with Ehrlich's triacid fluid it appears of a pale brownish colour, the peripheral band being often more intensely stained than that around the nucleus. The nucleus s round or slightly oval, rarely indented, and averages in diameter two-thirds of that of the cell. It is not as a rule separated from the protoplasm by a clear ring, as occurs so frequently in the case of megaloblasts. The nucleus stains of a homogeneous bluish green colour and shows no chromatin reticulum; there are, however, often several circular or oval paler areas. In these respects the nucleus agrees with that of the neutrophile myelocytes except that the latter are not so symmetrical in contour but usually show some elongation or slight indentation. In films fixed and stained with Jenner's fluid the protoplasm shows an intensely basophile reticulum, with frequently very marked "fraying" and "budding" at the margins. In contrast with the surrounding band of dark-blue protoplasm the nucleus appears much paler and shows no chromatin reticulum or nucleoli. From these characteristics it is clear that we have to deal with cells corresponding with the classical description of the large lymphocyte and differing from the large hyaline cells normally present in the blood in small numbers. The latter do not exhibit the marked basophile reaction of their protoplasm.

[3] Paton and Goodall: Journal of Physiology, vol. xxix., 1903, p. 411.

[1] A count done on a film taken a week previously gave practically the same result.

In heat-fixed films stained with Ehrlich's triacid fluid the neutrophile myelocytes correspond in general characters with the large hyaline cells except that their protoplasm shows granules of the usual violet tint. In many of the myelocytes the granules are so small as merely to give the protoplasm a *finely stippled appearance which is not confined* to one part of the cell but is evenly diffused. With Jenner's stain fine oxyphile (neutrophile) granules are scarcely apparent in these cells and where granules can be made out the protoplasm is not so markedly basophile as in the large hyaline cells. A differential count on a film stained with Jenner's fluid, where any cell showing the faintest trace of red is taken as finely granular oxyphile, shows a smaller percentage of such cells than does an Ehrlich film of neutrophiles, while the percentage of polymorphonuclears is in both cases practically identical. Thus probably some of the myelocytes do not show granules by Jenner's method and appear as large mononuclear cells with a narrow rim of protoplasm which is not more basophile than the nucleus—the "lymphoid cells" of Wolff. Appearances indicative of mitosis are to be observed both in the myelocytes and in the large hyaline cells.

Cells containing eosinophile granules are not numerous. Although they are set down as constituting 4·5 per cent. of the leucocytes only about 0·9 per cent. could be said to conform at all closely with the types of eosinophile cell met with normally in the blood and marrow of the adult. In heat-fixed films stained with triacid fluid the granules vary greatly in size in one cell as compared with another and also in the same cell; usually the granules are smaller than normal, but a cell containing granules double the usual diameter was seen. The majority are mononuclear: perhaps 1 polymorphonuclear form occurs in 20. In the myelocyte forms the granules assume the violet (neutrophile) tint, even when from their size they are undoubtedly of the eosinophile type. In the great majority the granules are sparsely distributed through the protoplasm of cells which otherwise corresponded in every respect with the large hyaline elements; in other instances the granules are aggregated at one side of the cell When the granules occur in such a hyaline cell in countable numbers and scarcely larger than the granules of a neutrophile polymorphonuclear leucocyte, their identity becomes open to doubt. It is only because one can trace all gradations from these to the typical eosinophile myelocyte that one can decide on their nature. With Jenner's stain only one cell containing coarse eosinophile granules was met with in the course of counting 700 leucocytes; it was polymorphonuclear. There are, however, mononuclear cells with markedly basophile protoplasm containing rounded basophile granules which show the same variations in size and distribution as are observed in the case of the eosinophile cells in films stained with triacid fluid. "Budding" of the protoplasm of these cells is frequently to be observed. Cells containing both eosinophile and basophile granules are definitely present although in very small numbers. If we count such cells with coarse basophile granules as eosinophile then the percentage is 3·5 as compared with 4·5 per cent. of eosinophiles in triacid preparations. On the other hand, if in both preparations we count only typical examples of eosinophile cells—i.e., coarsely granular eosinophile ones with Jenner and coarsely granular ones in triacid films—then the percentages are 0·15 and 0·9 respectively.

Both "wet" and heat fixed films were stained with basic dyes (polychrome, methylene blue, and carbol-thionin blue). These showed that mast cells are very scanty. The spherical granules with marked basophile reaction are not nearly so frequently to be made out here as in the Jenner films nor is their absence to be accounted for by the appearance of cells the granules of which, like the eosinophile granules normally present in the adult, appear as unstained refractile bodies (negative staining). In this connexion I may say that in some of the basophile granular cells in a film stained by Jenner's method I saw along with the markedly basophile granules others in the same cell which did not take up the eosin but were unstained. The coarse granules which do show a basophile reaction in films stained with basic dyes are not metachromatically tinted.

That these coarse basophile granules are in reality a modification of the eosinophile secretion (probably in the direction of a less mature product, as will be considered afterwards) is practically certain from the following considerations: 1. The regular contour of the granules and the absence of metachromatic tinting with basic dyes; both of which characters serve to distinguish them from mast-cell granules. 2. The characteristic way in which they are set free by the "explosion" of a cell containing them through rupture of its protoplasm in the course of spreading the film. 3. The occurrence of coarse basophile along with *coarse eosinophile granules in the same cell. 4. The* fact that the percentage of eosinophile cells is so small in a Jenner preparation as compared with a triacid one unless these cells containing coarse basophile granules be counted as eosinophile elements. A few cells are met with which possess small fragmented nuclei and scanty protoplasm. With triacid staining the nucleus appears dark and "pyknotic." Some of these cells possess coarse granules which appear to stain with triacid fluid, while with Jenner's stain they appear usually basophile, but sometimes they are oxyphile. These are probably to be regarded as degenerated elements.

So far as the appearances in the blood are concerned this case is undoubtedly to be classed as one of mixed cell leukæmia, since we have to deal with a great increase of colourless cells both of the granular and of the non-granular types. In addition, the large lymphocytes which are present in such numbers are elements quite as foreign to the normal adult blood as are the finely granular myelocytes. It is not necessary to suppose an affection of any other tissue beside the marrow, however, to explain such a blood picture as this case presents. If we believe that in leukæmia we have to deal with a "sarcoma of the blood" then we must be on the look-out for appearances indicative of a reversion to the embryonic type, which such a supposition would imply. There is good evidence that the blood in this case affords a marked example of such reversion. In proof of this I shall compare the appearances presented here with my observations[2] on the bone marrow of the human fœtus which accord in general with the results of Pappenheim,[3] Dominici,[4] Hirschfeld,[5] and others. In the femur marrow of the human fœtus at three and a half months and until between the fifth and sixth months the majority of the colourless cells are non-granular. They consist principally of mononuclear cells which possess a markedly basophile reticular protoplasm. With Jenner's stain the nucleus appears less basophile than the cytoplasm. It is to these undifferentiated leucoblasts that Pappenheim, Hirschfeld, and others have applied the term "lymphoid cell." At the early ages the protoplasm of these cells is more abundant and more ductile than later when they come to resemble exactly the large lymphocytes which are present in this case and which it seems reasonable to regard as a reversion to the type of the undifferentiated leucoblast. With regard to the appearance of granulations in the cells of the fœtal marrow, eosinophile myelocytes and polymorphonuclear cells in all respects similar to those present in the adult are already to be found in the marrow at three and a half months. At this age and until later dates (five months) atypical forms are present which are to be regarded as cells in the process of differentiation and young so far as granule formation is concerned. Such appearances are: (1) minute granules and variations in the size of granules in a cell; (2) restriction of the granules to one part of a cell, the protoplasm of the rest being markedly basophile and reticular; (3) scanty numbers of granules in a cell; (4) the assumption of the neutrophile tint by granules with triacid staining; and (5) a marked basophile reaction of the granules with basic dyes, metachromatic staining being absent, however; also the occurrence of both basophile and eosinophile granules in the same cell. All of these characters are met with in this case; but while the basophile reaction of young eosinophile granules is well known it is not often, I think, that the condition is so universal as in this instance.

[4] Dominici: Comptes Rendus de la Société de Biologie, *tome* i., p. 721, 1899.

[5] Hirschfeld: Virchow's Archiv, Band cliii., p. 335, 1898.

The neutrophile granules make their appearance at a later date than do the eosinophiles. They are not, as a rule, present in a notable number of cells in the marrow till between the fourth and sixth months. Prior to their appearance the myelocytes and polymorphonuclear leucocytes are non-granular and even at the sixth month I have seen non-granular polymorphonuclear cells in heat-fixed films of the marrow stained by Ehrlich's method. In the adult the granular leucocytes are the products of the mitotic division and nuclear transformation of mononuclear cells bearing similar granules (myelocytes); but it is probable that in the fœtus granules may begin to be secreted for the first time in cells which have become polymorphonuclear.

With regard to the question of the origin of granular cells outside the bone marrow, I am satisfied from my observations on the thymus in the human fœtus that both eosinophile and neutrophile leucocytes arise from the mitotic division of mononuclear granular cells lying in the loose connective tissue which runs between the lobules and in which the blood-vessels course; the same holds good of the liver (eosinophile cells were seen in the perivascular tissue of the portal vein in a ten weeks' fœtus) and prior to the granular cells we must have, of course, the undifferentiated leucoblasts. The connective tissue in these situations, however, undergoes a degree of physiological thickening which must within at most a few years after birth render it so dense as to hamper any extensive process of cellular proliferation and emigration into the blood vessels so that probably long before adult age is reached the leucocyte production existing normally in these situations in the fœtus must have come to an end. It is held by Pappenheim and others that the lymphoid cell gives rise to the red corpuscles as well as to the leucocytes. Nothing in the blood of this case lends support to the idea of the interdependence of these two classes of cells.

In conclusion, there is good ground for supposing that the blood in this case presents indications of a reversion to conditions which normally exist in the marrow in fœtal life. Such is the explanation of the abnormal eosinophile forms and it is to the reversion of the granular myelocyte to the non-granular "pre-myelocyte" or "indifferentiated leucoblast" or "lymphoid" cell or to the excessive proliferation of the few such cells which normally are present in the adult marrow with the resumption of embryonic activity that this case of leukæmia owes its "mixed" characters. This view is in complete accordance with the opinions expressed by Muir on this question at the annual meeting of the British Medical Association.

A number of cases of leukæmia and allied conditions are on record in which both the granular and the non-granular cells were increased. In Wilkinson's case[6] there was a great increase in the number of leucocytes in a woman, aged 35 years, with enlarged spleen but without enlargement of the lymphatic glands. The blood showed numerous myelocytes and large lymphocytes; eosinophiles and mast cells were increased; megaloblasts and normoblasts were present. Eight days later—two days before death—the blood was lymphocythæmic with the presence of only a few myelocytes. In the case recorded by Michaelis,[7] the patient, a woman, aged 50 years, complained of weakness and breathlessness and was under observation for three months before death. The blood picture was fairly constant: red corpuscles, 3,500,000 per cubic millimetre; a few normoblasts; and leucocytes, 116,000 per cubic millimetre. Differential count: neutrophile poly morphonuclears, 16·0 per cent.; neutrophile myelocytes, 7·2 per cent.; eosinophiles, 0·4 per cent.; mast cells, 0·4 per cent.; large lymphocytes, 56·0 per cent.; and small lymphocytes, 20·0 per cent. Cell forms showing differentiation from the non-granular to the finely granular type were observed in the blood. Post mortem the spleen weighed four and a half pounds. It consisted mainly of large non-granular mononuclear cells and giant cells with scanty myelocytes; marrow, ditto; giant cells were present both in the lymph glands and the liver.

Simon's[8] patient was a man, aged 42 years, who came under observation 18 months before death, complaining of indigestion. Blood examination at first showed red corpuscles 1,350,000 per cubic millimetre, leucocytes not increased, but 6 per cent. neutrophile myelocytes; eosinophiles and mast cells were absent; normoblasts and a few megaloblasts were present. Eight months later a blood count showed red corpuscles 3,968,000 per cubic millimetre; hæmoglobin, 40 per cent.; and leucocytes, 14,000. Splenic enlargement was now perceptible and the spleen increased till it reached the umbilicus. Ulcerative stomatitis supervened before death. No necropsy was made. Blood counts showed that the number of leucocytes rose in the last week of life to 116,000, never having previously been higher than 26,000. The neutrophile polymorphonuclears varied between 17·9 and 50·7 per cent; neutrophile myelocytes between 29·1 and 53·5 per cent.; eosinophiles none; mast cells, between 0 and 1·3 per cent.; large lymphocytes, between 4·9 and 55·3 per cent.; and small lymphocytes between 0·6 and 14·3 per cent. The later counts showed, as compared with the earlier ones, a marked increase in the large lymphocytes and a diminution in the neutrophile polymorphonuclears.

Fowler's case[9]—a girl aged five years—showed about 250,000 leucocytes per cubic millimetre, of which some 50 per cent. were large non-granular cells; neutrophile myelocytes were above 12 per cent.; eosinophile polymorphonuclears and myelocytes were present and mast cells from 3 to 4·4 per cent. Among the large non-granular cells some had intensely basophile protoplasm; others slightly basophile protoplasm, which was in some instances hyaline and in others contained fine granules ranging from basophile to neutrophile in tint. These were taken to represent stages in differentiation from non-granular to granular cells. In Wolff's two cases[10]—in adults—non-granular cells constituted 78 per cent. of the leucocytes, while 17 and 5 per cent. of differentiating forms were present. In a case of chloroma reported by Klein and Steinhaus[11] the leucocytes numbered 20,000, finally 41,000 per cubic milllimetre; lymphocytes rose to 66 per cent., 47 per cent. being large. Myelocytes were present in the blood throughout (from 16 to 32 per cent.). Post mortem the myelocytes constituted the greater part of the tumour masses but were not present in the spleen and glands.

The question which is raised by the occurrence of such cases as the above is whether we are dealing with a form of leukæmia in which both myeloid and lymphoid tissue are involved. The researches of Ehrlich served to separate the leukæmias into two broad classes: (1) the myeloid, in which the granular leucocytes are as a rule increased in the blood,[12] and where in addition the myelocyte forms find their way into the circulation, the proportions of the various granular forms (neutrophile, esinophile, mast cell) presenting wide variations from the normal; and (2) the lymphoid, in which non-granular forms predominate and are usually both absolutely as well as relatively increased, the small forms predominating as a rule in the chronic and the large ones in the acute cases.

In the normal adult the seat of proliferation of the granular cells is practically restricted to the bone marrow and this appears to be absolutely the case so far as the neutrophile forms are concerned; on the other hand, non-granular cells are found to multiply in the connective tissue throughout the body as well as in the lymph glands. Thus, not merely are the granular and the non-granular cells, on the whole, distinct in their seats of origin in the adult but they subserve different functions, as is shown by the reactions of myeloid and lymphoid tissue under pathological conditions—e.g., in the infections (Muir[13]), and there is no evidence that the cells of the one type become transformed into the other.

[12] In cases cited by McCrae (Brit. Med. Jour., vol. i., 1900, p. 760) the number of leucocytes fell at times to normal, with or without the persistence of myelocytes.

[13] Muir: Transactions of the Pathological Society of London, vol. liii., part iii., p. 379, 1902; also Journal of Pathology and Bacteriology, vol. vii., p. 161, 1901.

The progenitor of both the granular and the non-granular cell types in the fœtus, however, is the large mononuclear cell with non-granular basophile cytoplasm. Hence a reversion to the embryonic condition on the part either of myeloid or of lymphoid tissue will ultimately lead to the appearance of the undifferentiated leucoblast. The occurrence of these cells in unusually large numbers in the blood in a myeloid leukæmia will give rise to a mixed-cell blood picture and does not necessarily imply any participation of lymphoid tissue in the proliferative process. That these undifferentiated leucoblasts may, as in the embryo, perform the function of producing granules and thus become myelocytes is apparent from the observations of Wolff, Michaelis, and Fowler as regards neutrophiles, and as regards eosinophiles in my own case. As Hutchison[14] remarks, one would expect the reversion to the non-granular form to occur with greater ease in childhood and it is significant that very few cases of pure myeloid leukæmia have been observed in children.

It is well known that metastatic carcinomatous growths in bone may give rise to a blood picture resembling myeloid leukæmia (Kast[15]), owing to a disturbance of the myeloid tissue which may either be of the nature of a reaction or may be due to mechanical derangement. Similar disturbance of the marrow by proliferating lymphoid tissue serves to explain, as Hirschfeld[16] suggests, the small percentage of myelocytes which is occasionally found in the blood in cases of lymphatic leukæmia (Bradford and Shaw[17]). If the myelocytes appear in larger numbers, however, the blood picture will be of the mixed-cell type. Such may be the explanation of the case of Michaelis, *vide supra*, (Pappenheim[18]).

In conclusion, it may be said that until the etiological factors in the causation of leukæmias are understood it is impossible to decide whether both myeloid and lymphoid tissue may be involved at the same time, but it must be remembered that the blood picture is merely a symptom and that transient and explicable causes have produced similar conditions of the blood—e.g., in a case of acute pneumonia in a man, aged 54 years, 96,000 leucocytes, of which 86 per cent. were lymphocytes; a case of acute sepsis, 200,000 leucocytes, of which 12·2 per cent. were neutrophile myelocytes and 6 per cent. were basophiles. Recovery in both cases was accompanied by a return of the blood to normal (Houston[19]).

SUMMARY.

1. Myeloid leukæmia is due to a hyperplasia of myeloid tissue; but the unknown causative agent is irregular in its action, so that any of the various granular types may predominate or a mixed-cell blood picture may result from the reversion of many of the cells to the condition of the non-granular undifferentiated leucoblast or from the hyperplasia of such non-granular cells normally present in the marrow in small numbers. These undifferentiated leucoblasts may assume their embryonic activity and secrete granules.

2. In leukæmias a mixed-cell blood picture may be due to: (*a*) a reversion of myeloid cells to the embryonic non-granular type; and (*b*) a reaction or mechanical disturbance of myeloid tissue owing to lymphoid hyperplasia with as a result the passage of myelocytes into the circulation.

3. It is to be understood that it is left quite an open question as to whether or not myeloid and lymphoid tissue may be concomitantly affected in a way similar to what occurs in myeloid and lymphoid leukæmias respectively. If such occurred then we should have a *mixed leukæmia* in the strict sense.

NOTES ON ABDOMINAL SURGERY BASED UPON COMPLETED RECORDS OF 744 CASES.

By E. STANMORE BISHOP, F.R.C.S. ENG.,
HONORARY SURGEON TO THE ANCOATS HOSPITAL, MANCHESTER; OPERATING SURGEON FOR DISEASES OF WOMEN TO THE JEWISH MEMORIAL HOSPITAL, MANCHESTER.

A REVIEW of work in any specialty is always interesting and especially if it extends over a number of years and thus reflects the various changes which have taken place in the technique employed. To the operator himself certain points also become clearer and may perhaps be advanced with more confidence for the consideration and criticism of others.

Abdominal surgery covers a wide field. For some time it has been the fashion to limit that part of it which is only seen in women and which, indeed, depends upon their sex as a separate specialty. But there are not wanting signs that this fashion is upon the wane and that it is being realised more and more convincingly that such a limitation has no anatomical or clinical ground for justification. That any man who opens the abdomen must be prepared to deal with whatever he may find within is, one would think, self-evident, and if that is so abdominal surgery is a far more fitting term to describe the work done than mere gynæcology. The most recent works on gynæcology describe operations upon the bladder and intestine, and necessarily so, since these organs are frequently implicated in purely gynæcological diseases, such, e.g., as pyosalpinx. It cannot surely be pretended that such organs occur only in women. Two cases which have occurred in my practice amongst others may serve to illustrate and emphasise this point.

CASE 304.—In March, 1898, I was asked by my friend, Dr. G. Knapton of Manchester, to see with him a woman, aged 35 years, who complained of great pain in the left iliac fossa which had lasted 21 years, always becoming intensified at the menstrual periods. This fact had, no doubt, strongly impressed the mind of a surgeon, one who practised pure gynæcology, who had removed both her ovaries in the previous July under the belief that they were cirrhotic and therefore the cause of her suffering. Whilst convalescing and lying in bed the pain was certainly easier but it recurred as soon as she began to go about and was at the time of examination, if anything, more severe than before. She had been seen by a physician in Manchester who advised that the ligatures around the ovarian stumps should be removed, as, in his opinion, the pain was due to the inclusion of nerve fibres in their grip. Closer investigation, however, brought out certain facts. First, the pain had been present for one year before menstruation began at all. Secondly, it always started below the left lower ribs and passed downwards, shooting towards the pubes and the left leg. As long as the pain was confined to the upper region it was bearable but when it passed downwards morphine was required to relieve it. Thirdly, during the presence of the pain there was an incessant desire to micturate and she would spend a considerable time endeavouring to pass urine, which was always impossible until the pain relaxed, when a little urine would pass, the passage of which caused great pain which was now referred to the urethra. After the first passage urine would be passed again in fair quantity four or five times in half an hour. Examination (recto-bimanual) discovered a rather large calculus fixed in the lower end of the ureter. This was removed through the bladder by suprapubic cystotomy and the pain disappeared entirely.

CASE 573.—In April, 1903, I was asked by my friend, Mr. R. P. Lawson of Openshaw, to see with him a relative who had been under the care of a gynæcologist who had operated with a view to the removal of her ovaries which were believed to be diseased. Finding on opening the abdomen that both were healthy this operator had reclosed the abdomen. The patient had complained of pain in the right iliac fossa for four years. This had been of a gnawing character and passed down into the right leg; until lately it could be relieved by lying down and removing all clothing from the part; but at the time of examination it was continuous and position had no effect. The pain was accurately localised by the patient at a point slightly below McBurney's point. The attacks had been more frequent and more severe during the last 12 months. The pain was associated with nausea but there was no vomiting. The action of the bowels was regular and did not affect the pain. There were well-marked dulness on percussion above the right Poupart's ligament and an equally distinct swelling with a crescentic upper margin, convex upwards, with the ligament as a base. The pelvis was clear and the uterus was moveable and anteflexed. On May 3rd, 1903, the appendix was removed by the usual incision and was found to be kinked. It was also adherent at its tip. The pain immediately subsided and has not since returned.

My abdominal operations number considerably over a thousand but I have only complete notes of 744 and it is upon these that I have based what remarks I propose to make and from which I have drawn illustrative cases for reproduction. The records themselves go back for nearly 20 years. This, whilst it prevents the declaration of the low mortality which is increasingly becoming possible, adds to the interest, since they supply specimens of most of the operations which have been practised and show to some extent the elaboration of the present methods. As I have not been restricted by the necessity of having to teach students certain definite procedures for the purposes of examination I have perhaps been able more easily to adapt my work and methods to any improvements as they have been introduced. But it would be clearly impossible to reproduce each case of so long a list except in such an abbreviated form as entirely to destroy any interest they may possess. I propose, therefore, to give the numbers of each class with their mortality, whilst one or two, or more, of those which appear most worthy of reproduction are given in detail.

Ovarian cystomata.—Of these I have operated upon 114. The mortality has been 7·8 per cent. This is a large mortality compared with that at present usually obtained, but all but two of these deaths occurred 15 years ago, when the technique of the operation was not so well understood. Of these two cases last mentioned one, detailed below, was that of an immense multilocular cyst, such as is very rarely seen now, adherent all over the anterior abdominal wall and to the entire under surface of the right lobe of the liver, which oozed freely after the cyst wall had been peeled off it. In the other a multilocular cyst was buried beneath densely adherent Fallopian tubes full of pus with an abscess in the uterine wall and the case should probably be rather classed as one of double pyosalpinx. The ordinary ovarian cyst now presents but little of interest to surgeons and the ease and safety of the present operation contrast vividly with that of the time of Spencer Wells, whose operations I was privileged to witness on several occasions. The case to which I have referred above is here given.

CASE 679.—The patient, aged 40 years, was sent to the Ancoats Hospital by Dr. Ursula D. Fowler of Manchester on May 4th, 1905. The patient first noticed a swelling in the abdomen four or five years ago. This caused no discomfort and the increase in size had always been gradual. Difficulty in walking and increasing dyspnœa had been noted for 12 months. The menopause occurred in 1904. She had never been tapped. On examination on May 6th the abdomen was found to be enormously distended, measuring in circumference 46 inches. It was dull all over and gave a modified thrill. The veins were dilated in the upper half of the abdomen.

The operation was carried out on May 8th, the patient being placed in the Trendelenburg position. A median incision had to be carried upwards to the mid-point between the umbilicus and the xiphoid cartilage. The cyst was adherent to the anterior abdominal wall for the whole distance and for four inches in width, also to the under surface of the right hepatic lobe and to the omentum and the duodenum. It contained 17 pints of fluid and sprang from the right broad ligament. One and a half pints of saline solution were transfused while the patient was on the operating table. She died on May 9th.

The most noteworthy point in the case appeared to be the existence of these widespreading and firm adhesions in a patient who had never been tapped. In all previous cases where adhesions to the anterior wall were noticed paracentesis had been carried out several times and the complication has usually by most surgeons been attributed to this measure, which in earlier times was always practised before any attempt at removal was made. Here, as I have said, there had been no such preliminary interference and yet the adhesions were the firmest and most extensive that I have ever seen.

Fibroid disease of the uterus.—The cases in my list number 96. Of these the first three, operated upon between 1890 and 1894, were fatal. The first two were examples of extraperitoneal hysterectomy, the pedicle being brought out of the abdomen and fixed in the abdominal wall. The third was a fibro-cystic tumour springing from the uterine fundus and it was removed by a wedge-shaped incision, the cut uterine surfaces being afterwards sutured together. A glass drainage-tube was placed in Douglas's pouch and drainage in this direction was carried out by means of a syringe and tube by which its contents were from time to time removed. The patient died on the second day evidently from sepsis. Both these methods are now obsolete.

In 1897 Clark of Johns Hopkins University showed the futility of suprapubic abdominal drainage in these and similar cases and its harmfulness and since that time I have totally abandoned its use. Although I was fortunate enough to see the late Lawson Tait operate upon this class of case by his own operation of removal of the ovaries I have never practised that method. In one case I started with that intention but the left ovary was buried between two masses of fibroid growth and the whole front of the tumour was covered by large veins beneath the peritoneal coat. An attempt to ligature the ovarian artery on this side set up so much and such uncontrollable oozing of dark venous blood that I was forced to abandon the idea and proceed to entire removal. Soon after I became impressed by the writings of Brown-Séquard, Dunn, and Curatulo as to the value of the internal secretion of the ovaries and I saw enough of the evil results which followed removal of both ovaries for tubo-ovarian abscess during operations for double pyosalpinx to convince me of their truth, so that I have no examples of this method which I then determined to avoid. Tait himself made certain admissions which detracted much from the force of his previous strenuous advocacy. In certain cases he had found that good results were greatly delayed, in one case for two or three years. This was a serious drawback in such cases, which then were only operated upon when the patients were exsanguinated by the furious losses of blood; they bore operation badly, and a rapid check to the bleeding was the one thing required. Obviously a measure which required so long for its action to become effective left a good deal to be desired. Death might very well take place whilst its result was awaited.

In common with all other abdominal surgeons I was greatly impressed by the accounts received from Paris of the work of Apostoli and by the elder Keith's impassioned advocacy of his method of electrical treatment. At some considerable expense I obtained all the necessary instruments and treated a few cases in this way but it rapidly became evident that the positive pole was only a neater and more effective way of using a cautery, whilst I could never satisfy myself that the negative pole produced any results at all worth consideration. The craze lasted for a time and then died out. Tait, Martin, Mackenrodt, and others reported cases followed by distinctly evil results, and now, I suppose, there are not more than three or four men, if so many, who advocate electricity as a serious treatment for fibromyoma. Meanwhile the methods of removal of the actual tumours themselves became greatly improved and simplified, the two greatest advances, so far as I know, being the panhysterectomy of Christopher Martin and Landau's splitting operation, a modification of which is known as morcellation. The former operation I have performed 46 times, in 12 of which I have carried out the combined operation, commencing from the vagina, separating off the bladder, opening Douglas's pouch and tying both uterine arteries before opening the anterior abdominal wall. By this means, although from the first it was recognised that the later steps would have to be carried out through the abdomen, either because of the mere bulk of the tumour or because it was complicated, as this condition of the uterus so often is, by pyosalpinx, the abdomen was kept open for a much shorter time than would otherwise have been necessary and the whole work was accompanied by less bleeding because the main vessels, the uterines, were ligated early in the process. It has often proved to be a very difficult thing to obtain control of these vessels from above. The mass of fibroid is greatly in the way; it grows often irregularly and may press the uterine arteries much out of their normal position above or bury them beneath it. From below these vessels, on the contrary, can easily be found and secured in the majority of cases. But of course such a proceeding involves necessarily, just as vaginal hysterectomy involves, the loss of the cervix. It has always been a source of profound wonder and admiration to the writer to see the anxiety of some operators to save the cervix. For several years the so-called supravaginal amputation of the cervix was the most vaunted operation and even yet, as in one of the medical journals of June of this year, a well-known surgeon advocates the French modification of this operation—*l'hysterectomie subtotale*—and brings forward a string of cases to support it. With these operators there is apparently nothing so highly prized as this bit of tissue. At first the cervix was cut straight across at or about the level of the internal os Then, as it was found that pus sometimes accumulated about its upper end, necessitating dilatation of the remaining cervical canal in order to liberate it, the canal was variously treated at the time of operation. It was mopped out with strong carbolic acid, it was cauterised by the Paquelin or electric cautery, it was dilated and gauze drawn through, it was cut out—the whole remaining cervix was split and a wedge removed containing the canal; it was shaved down and the fragments reunited. We were told that it was the keystone of the pelvic diaphragm, that without it the pelvic contents would prolapse, that if entirely removed the vagina would atrophy and become senile, that by its removal the ureters would almost infallibly be damaged, that it prevented infection from the vagina, although a canal, and often a septic one, passed down its centre connecting that cavity with the raw surfaces above and although at the same time vaginal hysterectomy, which necessitates its removal as a primary step, was growing in favour and was admittedly not followed by all these terrible results. There were several plain reasons why it should go, not the least of which was the subsequent degeneration of it, in some instances, by carcinomatous changes in after years, but, in spite of all, certain surgeons still clung desperately to it as all-essential. They seemed to say, to parody a well-known rhyme:—

Let abscess, sepsis, cancer risk our patient's life,
But leave us still the cause of all this strife,
Our bit of cervix!

When the uterus has been removed, however, the pelvic peritoneum has always, if possible, been closed. In the majority of cases this is not merely possible but easy. The ligatures upon the tubes at each side are left long. Toothed forceps secure and draw down the peritoneal flap hanging from the bladder in front and the rectum behind. The tubal ligatures are drawn upon, so that the ends of the tubes are brought beneath the level of the flaps; these latter are sewn over and to them by a continuous catgut suture which closes entirely the peritoneal cavity, which now needs no drainage, since all the raw surfaces are outside it. A light gauze packing is laid between the raw surfaces of the base of the bladder in front and the raw broad ligament surfaces on either side. This is withdrawn in three days' time and is not replaced. By that time the peritoneal cavity is absolutely closed; the raw surfaces beneath can safely now be treated by irrigation daily, since no fluid can find its way into that cavity and the relief to the patient, who now no longer needs to dread the packing of new gauze between tender surfaces, is immense. No decomposing material can accumulate since the lower opening is perfectly free and granulations rapidly fill up the steadily contracting space. The whole process usually takes about three weeks, sometimes even less. Another great advantage of this plan is that the omentum and intestines have now no raw surface or edge to which they may become adherent. They move smoothly over a perfectly smooth peritoneal floor. They cannot escape into the vagina as has happened more than once when the whole vaginal outlet has been left open. Four cases are, perhaps, worthy of more detailed remark and may serve to illustrate most of these points. I take one from 1893, a case treated by extraperitoneal fixation.

Case 88.—The patient, aged 38 years, who had been married for 20 years, had had three children, the youngest of whom was 13 years of age. She was admitted to hospital on April 17th, 1893. Menstruation had commenced at the age of 15 years; it was normal, regular, and painless. Three years previously to admission the patient had suffered from hæmorrhoids and an ischio rectal abscess. Seven years before examination she had received a kick in the abdomen and six months later she first noticed some swelling. This was associated with intermittent pain; during the last six months the increase in the swelling had been far more rapid and the pain which had always been more marked on the right side had become constant. Examination showed a greatly enlarged abdomen with a circumference at the umbilicus of 38 inches and a vertical measurement from the xiphoid tip to the pubes of 16½ inches. The main swelling lay obliquely in the pelvis, its rounded fundus lying in the right iliac fossa. In the middle line and above lay a smaller mass intimately connected with the former. The uterus was carried high up in the pelvis out of reach by the finger in the vagina.

Operation was proceeded with on April 24th, the dorsal position being adopted. A long median incision was made from the pubes to two inches above the umbilicus. The omentum was adherent to the upper mass. These adhesions were tied and cut. The tumour was turned out of the abdomen; it appeared to extend from one side to the other of the pelvis. An elastic cord was carried round its base and tied. Strong pins were passed through the pedicle below this. The main tumour was then cut away; it included the uterus above the internal os which was imbedded in the mass, which appeared to grow from the back and sides of that organ. A strong wire loop was placed in the groove made by the elastic cord and tightened up. When this was tight the cord was removed. More of the growth was dissected out, the wire being still further tightened as this was taken away. Some vessels were tied on the surface. A glass drainage-tube was placed behind in Douglas's pouch. The parietal peritoneum was then united to the stump all round except where the Keith's tube lay. Whilst closing the abdomen hæmorrhage came on, necessitating a reopening of the wound and the ligature of a vein behind the stump. The collapse was very great. Ten ounces of normal saline solution were injected into the median basilic vein. Death from shock occurred on the 26th. The tumour weighed 16½ pounds. The loop was found to have nipped the fundus of the urinary bladder.

Case 502.—This case was treated by panhysterectomy. The patient, aged 57 years, was sent by my friend, Mr. J. E. Harburn of Buxton, in May, 1902. She had been married for 27 years and her only child was now 25 years of age. Menstruation had always been regular until 18 years previously, when an increased flow was first noticed. One year later intense flooding suggesting a miscarriage was experienced. From that time she had lost greatly at each period and was usually in bed for a fortnight and on a couch for the next fortnight in order to recruit, "the flooding was so tremendous." She had consulted various well-known surgeons, amongst them the late Sir Spencer Wells. He and most of the others counselled patience until the arrival of the menopause, as the tumour was very large, and it was feared that she would not survive any attempt at its removal. Another person consulted was Mattei, at that time famous for his bottled blue and pink electricity. About a year preceding examination urination had ceased for three days, during which time she had suffered greatly. The abdomen became distended and there was intense pain over the lower abdomen and the right kidney. After frequent hot baths and fomentations a little urine passed; this was succeeded by a large clot and some fluid blood, after which the secretion became again normal. This was the only severe attack of the kind but from time to time micturition with passage of pus and blood mixed with it had been more frequent than usual, and such occurrences had been accompanied by some pain in the right renal region. There had never been any difficulty in defæcation but diarrhœa had been present occasionally. She was examined on May 15th. There was a large irregularly shaped mass in the hypogastrium spreading into both flanks, but especially towards the right side. The abdomen was pushed forward below. Portions of the mass were extremely hard. All the outlines, however, were distinct and rounded. The os was carried high up and was somewhat fixed. Its lumen was patulous and a very offensive discharge issued from it. The broad ligaments appeared to be free near the pelvic wall on either side.

The patient was operated upon on May 17th. A long median incision was made from the pubes to two inches above the umbilicus. The abdominal wall was very thin. A large amount of œdematous omentum containing large tortuous veins was adherent mainly to the upper pole of the uterus which, greatly enlarged, formed the centre, with two wings formed by calcified subperitoneal fibroids springing from either side. After separation of the omentum the left infundibular ligament was tied and divided and the bladder was separated in front. There were several broad membranous adhesions between the top of this viscus and the tumour. Then the right infundibular ligament was also tied and divided; both ovaries were left. The vagina, being made to project by a long curved forceps passed up into the posterior fornix, was cut through from above and the os was seized by Doyen's erignè and pulled up. As this was drawn up the vagina was divided all round and the uterus was peeled off the remaining attachments to the bladder. The uterine arteries were tied and divided. The mass was then cut loose and removed. It weighed 7 pounds 13 ounces. All ligatures were cut short and the pelvic peritoneum was united over gauze drawn through into the vagina. The anterior wound was then closed. The mass removed was composed of several large tumours. One very large one on the left was calcified. Another in the centre springing from the fundus uteri was pedunculated with a very thick pedicle. The uterus itself contained many fibroid masses; one especially was partially extruded from the left wall into the uterine canal and had at its lower extremity been so gripped by the internal os that all below this point was gangrenous. The operation lasted two hours. The patient returned to bed with a temperature of 98° F. and pulse of 80. With the exception of the formation of an abscess, which was opened in the left inguinal region and drained, she made a very good recovery and lived in perfect comfort for two years. At that time a subperiosteal sarcoma appeared in the right humerus at its upper extremity and spread rapidly over the scapula, causing death in about eight months.

CASE 354.—Landau's method was adopted in this case. The patient, aged 43 years, was admitted on August 22nd, 1899. She had had one child who was now 21 years old. Menstruation had commenced at the age of 18 years and was regular up to the only pregnancy. The labour was a lingering one and the patient had never been well since. Menstruation commenced again afterwards and was regular during lactation and since. There had been no miscarriages. She was first seen in April, 1899. At that time there was a tender mass in the right iliac fossa which she had noticed for two years and to which her attention had been drawn by its having caused her to vomit and the pain in this region produced by that act. There had been constant heaving and regurgitation of food ever since. The right Fallopian tube was found to be full of pus at that time and was removed by abdominal section but the uterus appeared to be normal in size and shape. In August, 1899, she returned, complaining of fresh pain and the uterus was then felt to be enlarged, tender, above the pelvic brim, and irregularly bossed. The enlargement was mainly to the right, the rounded masses being hard, smooth, not elastic, with clean, well-defined outlines, and evidently intimately connected with the uterus.

On August 29th a vaginal hysterectomy by Landau's method was performed. Douglas's pouch could *not* be opened in consequence of the adhesions. After freeing the uterus anteriorly it was split centrally; as this advanced the adhesions above became still plainer and the uterine fundus was peeled out of them. During the splitting the scissors encountered and split several fibroid masses which were peeled out of their capsules, thus greatly diminishing the size of the uterus and permitting it more easily to descend. When the split uterus was brought down a large elastic mass was found fixed by adhesions in the position of the left ovary. By tying and dividing the now tense round ligament and peeling away from the left broad ligament it became possible to enucleate the mass from below and in front upwards and backwards. When delivered it proved to be the left ovary and tube which formed a tubo-ovarian abscess. The pelvic peritoneum was closed by suture, all ligatured parts being drawn below. These ligatures were now cut short and the vagina was loosely packed with gauze which was removed on Sept. 3rd. The patient made a rapid recovery, as nearly all these vaginal enucleations have done, in marked contrast to those of the same class treated by abdominal section.

CASE 355.—This case was treated by the combined operation. The patient, aged 65 years, was sent by Dr. R. T. Parkinson of Manchester on April 23rd, 1899. She had been married for 43 years and had had seven children and two miscarriages. Menstruation had commenced at about the nineteenth year of age. At that time it was irregular owing to anæmia. It was regular up to the age of 54 years, but afterwards was irregular up to 60 years of age, when it ceased. Eight years previously to examination a polypus was removed per vaginam by another surgeon. The patient was fairly well afterwards for some weeks but then she began again to have floodings and pain, especially on urination. For about five years an extremely offensive discharge had appeared and she had been considered to be suffering from carcinoma, apparently for this reason, by other medical men who had seen her. She was examined on April 23rd, 1899. The os was widely dilated. A foul-smelling, brownish, watery fluid was escaping, mixed with cheesy-looking débris. The uterus itself was large, mobile, rounded with irregular projections, also with clean, rounded outlines passing, but with no infiltration, into the broad ligaments on either side. There was a very troublesome cough with bronchial expectoration.

The operation was carried out on April 27th. First stage.—The patient was placed in the lithotomy position. The cervix was stuffed with gauze and sewn up. The bladder was separated off for some distance. Douglas's pouch was apparently opened and the vaginal wall was divided all round the cervix. The broad ligaments were tied and divided for about one and a half inches on either side. As there was troublesome hæmorrhage from the posterior wound *five forceps were left on.* Second stage.—Placing the patient in the Trendelenburg position the abdomen was opened by a median incision. The left Fallopian tube was tied and divided near the uterus. The wall of the uterus was greatly thinned and it tore during manipulation, liberating some foul material which was caught on sponges which had been packed around and beneath. There was a veil-like broad adhesion behind which was divided. The bladder was entirely separated in front. The opposite tube was also tied and divided and the uterus was removed. There was still considerable venous hæmorrhage from the edges of the divided broad ligaments. These were clamped but as the patient showed increasing signs of collapse a gauze drain was drawn through into the vagina, its upper extremity being flush with the peritoneum; the clamps were left and the abdominal wall was closed up to and around them. Once or twice during the ensuing 24 hours collapse was again threatened but it was averted by transfusion of saline solution and other measures. The forceps were removed on the 29th. The lower part of the abdominal wound was covered by slough. Very foul discharge came from the vagina. A very anxious time followed. The gauze was removed from the vagina on the 30th, on which day some flatus passed per anum. The urine at first was passed unconsciously but control was soon recovered. The bowels were opened on May 1st. The facial expression was for a long time extremely bad but the pulse remained slow and full and there was no rigidity of the abdomen. Large black offensive sloughs were removed from the abdominal wound which was dressed with glutol and pure phenol and later with ichthyol ointment. Fluid passed freely through from the abdominal wound to the vagina and *vice versâ* during douching until the 6th, when the communication became blocked by repair. Ultimately the patient recovered perfectly and that winter she for the first time for eight years spent Christmas with her children. Before this she had been prevented by the foul smell of the sloughing fibroma from mixing with any of her relatives.

Considering the safety of hysterectomy at the present day—I have not seen a single death after the vaginal operation for the last three years—is it still considered wise to advise patients suffering from this disease of the uterus to postpone operation in the often futile hope that the menopause will bring an end to their sufferings? In Case 502 the change of life had been looked for as a certain cure and was still being hoped for at 57 years of age. Fortunately she fell into the hands of a man (Mr. Harburn) who recognised the unwisdom of this course of action, saw that the loss of blood was not being made up in the intervals, and advised operation. This delay in what is th
only absolute cure can only decrease the chances of su
when at last operation is decided upon but it is pa
frequent even now. Should there be the least suspi
malignant disease of the uterus medical men are
enough to advise removal at the earliest opportun
look upon delay as almost criminal. It is right and
that this should be so. No one can attack carcin
disease too early but how often after such an o
has been primarily perfectly successful have we
deplore recurrence of the growth or its s
appearance elsewhere? In pure fibromyoma
uterus is removed there are no such regrets. T
tion is done, the growth and the organ in
grew have gone, and being non-malignant an

to that organ cannot recur. If fibroma is liable to sarcomatous degeneration, as would seem to have occurred in the case quoted, that is a late change and is only another argument for early removal. The fibroid change in the uterus in Case 502 had obviously been present for 20 years. If the sarcoma which appeared in the patient's humerus two years after hysterectomy was really, as we may suspect, secondary to the uterine growth, will anyone maintain that it had been present in that growth for the whole 20 years? and if not there must have been a time when removal of the fibroid uterus would not merely have stopped the excessive hæmorrhages from which the patient suffered so long and which practically debarred her from the enjoyment of life—which in all other respects her surrounding circumstances and her own disposition combined to render a very pleasant one—but have preserved her from the terrible disease to which at last she fell a victim. In carcinoma we do our best, but we too often fail in consequence of the very nature of the disease for which we operate. In fibromyoma the same proceeding brings about a successful and *permanent* result but with some medical men the operation is practically tabooed for this very reason—because the disease is not malignant and therefore will not immediately kill the patient.

One other objection to these operations which, I understand, is still made in some quarters, that the operation brings about acute menopause and so endangers the mental condition, is obsolete, because in these later operations the ovaries are left. In most cases which I have seen the mental as well as the physical condition immediately and permanently improve because the ovaries and the brain are no longer starved of their proper supply of blood. As time goes on one finds it more and more possible to complete these and similar operations through the vagina and the gain to the patient in rapid recovery and to the surgeon in loss of anxiety is extremely great.

Carcinoma of the uterus.—Cases of carcinoma of the uterus have been always treated by removal by the vaginal route. Of these I have seen a large number but have only operated by hysterectomy upon 19. I have since my earlier experiences made it a rule to attempt no case in which the disease had spread into the broad ligaments. So far I have read and have heard no evidence which has seemed to have sufficient force to induce me to do otherwise. I have, however, always explained to the sufferer or her friends that some other operators do not hold the same views and left them free to consult those who might be more daring. So far none of such patients have come back to me 18 months later to convict me of cowardice. Any who have preferred to remain have been treated by free curetting and the application of Paquelin's or the electric cautery, and these measures, with the free application of a mixture of orthoform and glutol, have appeared to give results at least comparable to those of other operators who have practised extensive removal of lymphatics and glands—Schuchardt's (the latest) operation included. The usual duration of life after the case was first seen has been about 16 months. Three of my cases in which the disease was confirmed by reports from the Clinical Research Association or other trustworthy microscopists are still alive and well more than three years after operation, one 11 years, one seven, and one just over three. From eight of the others my letters of inquiry have come back through the Dead Letter Office, four have been operated upon during the last three years, and though all living are not yet old enough to speak about. The remaining four I know to be dead from recurrent or secondary growth. I strongly suspect that the eight who have not replied are also dead in the same way. It is a relief to turn to more satisfactory lines of work.

Ectopic pregnancies.—I have seen and operated upon 13 of these and with them I have been very fortunate, since so far I have had no fatality. Four cases are given in detail below.

CASE 299.—The patient, aged 20 years, had been married for 16 months and had had one miscarriage. She was admitted to hospital on March 2nd, 1898. Menstruation had been perfectly regular until two months previously to admission; at that time her period was delayed for 14 days. When it recurred it was followed by an irregular discharge of shreds and clots which continued up to the time of her admission. Pain in the left inguinal region was first noticed on Feb. 26th. Its onset was sudden, whilst the patient was kneeling cleaning the floor. This had recurred in paroxysms ever since, with a great deal of nesmus. Vomiting occurred twice during the missed tnight but not again until March 2nd, since which time it was incessant until operation. There were some dragging of the left leg and some sharp pain during urination. Bimanual examination showed a boggy mass in the left fornix and pulsation in the uterine artery below was rendered more palpable. This mass was of uneven consistence, being distinctly boggy in places. The shape was that of a German sausage, about three inches long. The pulse was 68, the temperature was 99·4° F., and the respirations were 16.

On March 4th an abdominal section was made. The left tube was ruptured and contained black clot. Some dark blood and clots were found in Douglas's pouch and some also amongst the intestines. Both the left tube and ovary and all clots were removed. The right Fallopian tube was swollen and elongated but it was left as it seemed capable of recovery. The uterus was slightly enlarged, reddened, and roughened. It was not touched. The abdomen was closed. Perfect recovery followed and the patient was discharged from hospital on April 27th.

CASE 352.—The patient, who was 27 years of age, had been married for six years and had had two children but no miscarriages. She was admitted to hospital on March 9th, 1899. Menstruation had commenced in her eighteenth year and had been regular and painless up to the time of her marriage. Her last child had been born four years and nine months prior to admission. Lactation had extended over 14 months. The periods had returned 12 months after labour; then there was amenorrhœa for two months, after which it became regular. Three and a half months previously there had been a missed period; the next period was also absent. One month before admission a brownish-red discharge appeared which persisted up to the time of operation. On Feb. 18th she had passed a flesh-coloured mass, a second and smaller piece coming away a few days previously to admission. Pain in the hypogastrium and in both inguinal regions was said to have been present since September, 1898, and had become steadily worse. This pain, which was paroxysmal, was accompanied by syncope and occasionally by vomiting. She was examined on March 9th, when a soft doughy mass was felt behind, and to the left of, the uterus which was itself not much larger than normal but was pushed, cervix and all, over to the right. The mass was of uneven consistence and its outlines were vague. There had been some difficulty in defæcation for a fortnight. The straining always intensified the pain and during the last week this pain had been felt down the right leg as far as the ankle.

On March 10th an abdominal section was made. The omentum was adherent in front to a tense purplish tumour which occupied the left broad ligament, bulging into, and closing, Douglas's pouch and extending up to the pelvic wall. The small intestine was also adherent above. The mass contained large clots; these were carefully removed but no ovum was seen. The opened-up broad ligament was closed by silk suture and the abdomen was closed. Perfect recovery followed, the patient leaving the hospital on the 24th.

CASE 493.—The patient, aged 36 years, had been married for 17 years and had had 11 children, one miscarriage occurring between the first and second full-time children. She was admitted on Oct. 27th, 1902. The youngest child had been born six months before admission. The infant was suckled until its death four months later. The last period seen was in the first week in the month of September. When this period began it was accompanied by great pain in the right sacral region. The flow was much more than was usual and the period may have been a day or two later than normal but there had often been irregularity in date even before marriage. The pain decreased as the flow became established but it never subsided completely. It passed down both legs nearly to the knees. Since this period there had been the sensation of commencing menstruation every day. On the 23rd the patient had felt pretty well on rising and during the morning but at 12.30 noon sudden intense pain was felt in the epigastrium, rendering her unconscious. On recovery she was cold, sweating, and nauseated. There was no vomiting. This pain lasted with intermissions until her admission, occasionally passing into the right iliac region but never into the left. When it was felt on the right side she at once again became faint with cold sweating. There was some general abdominal swelling since the 23rd up to the time of operation. The breasts were not enlarged. The patient was extremely pallid with a rapid shallow pulse. There was some dulness in the right inguinal region There had been absolute constipation since the 24th.

Operation was proceeded with on Oct. 27th. An incision was made in the outer edge of the right rectus, as we could not be sure that we might not be dealing with a ruptured appendix. On opening the peritoneum large quantities of bright fluid blood mingled with black clots escaped as if under tension. The uterus was pulled up and the right Fallopian tube was found and was clamped close to the uterus and the infundibular ligament outside the fimbriated extremity. Still the bleeding continued and there was some doubt as to its source until it was found that the omentum, which had been adherent and which was separated rapidly in order to reach the mass, had retracted to the left and that the blood was coming from a vessel in it now out of sight. It was recaptured and tied; all bleeding now ceased and the old clots were carefully removed. The tube was tied off and taken away. The patient was transfused with two pints of saline solution by the median basilic vein and half a pint under each breast. The abdomen was closed. The patient was somewhat collapsed but after the transfusion she rallied pretty well. On the 31st pain over the right chest was experienced and there was some discharge of clots per vaginam. An abscess formed in the right pleura, which was opened on Nov. 5th. On the 17th some fluid was found on the left side and liberated. Ultimately the patient recovered entirely and returned home.

CASE 278.—The patient, whose age was 28 years, had been married for 11 years and had had four children and one miscarriage. She was admitted to hospital on Sept. 14th, 1897. The birth of the last child had taken place three and a half years previously and the patient had never been well since. The confinement had been tedious and was said to have lasted for five days, a midwife being in attendance. Before getting up from confinement she had noticed pain in the left inguinal region. This had been intermittent ever since. She was in bed for two months. The left leg also had been painful and aching but never swollen. Menstruation had been regular ever since up to July, 1897, when for a period of eight weeks there was no flow. On August 21st and ever since blood in slight quantity had been passed but no shreds or membranes. Sleep was now interrupted by gnawing pain which would come on suddenly and would last for five or six hours and then slowly subside. During each period of pain the flow of blood increased. Her temperature on admission was 100·2° F. On examination the os was found to be open and the cervix to be split The uterus appeared to be in the median line and but slightly enlarged. Behind, in Douglas's pouch, was a soft elastic mass extending towards the left side. The uterus could be defined as distinct from this. The mass was of uniform consistence. The broad ligaments were free on the right but vaguely blended with the mass on the left. In the left fornix the uterine artery could be felt pulsating.

On Oct. 4th an abdominal section was made. On opening the abdomen a multilocular ovarian cyst presented itself of about the size of a cricket ball. The right tube was closed and swollen. These were removed and below a collection of black clot was found in Douglas's pouch, over which was spread out the left Fallopian tube, in the lower surface of which was a rent and the lumen of which still contained a large clot. The tube had given way near its uterine extremity; the main swelling appeared to be outside the inner half of the tube. All these tissues were covered over, and fixed, by adhesions which, however, easily gave way. The whole diseased and ruptured tissues and blood were cleared away; the left ovary, being healthy, and the uterus were left. The abdomen was entirely closed. The patient rapidly recovered without any bad symptom and was discharged well on the 23rd. She returned to hospital on March 5th, 1899, with retroflexion with adhesion. Ventro-suspension was performed on the 7th, all adhesions being freed and she went home free from all discomfort on the 24th.

It may be noted that all these ectopic pregnancies were attacked from the abdominal side. I believe that certain accomplished surgeons have succeeded from the vagina but I know of one case where this method had to be abandoned owing to hæmorrhage from the ovarian artery which could not be controlled because of the adhesions above which would not permit of the delivery of the tube downwards. The abdomen had in the end to be opened and the patient died, exhausted by the loss of blood. It has always seemed to me far safer to go at once for the source of the hæmorrhage by the route which gives the most rapid access. Once the abdomen is opened it is the work of a few seconds to apply two clamps—one to the uterine end of the tube to control the uterine artery and the other to the infundibular ligament to control the ovarian. Once these are clamped no further blood can escape except from adhesions and the cleaning-up can be done with more leisure and with perfect safety. In Case 493 it would have been impossible to detect or to reach the vessel in the omentum, which would equally have been torn through if the operation had been attempted from below. None of the arguments which in ordinary cases tell so much in favour of the vaginal route, neither the more rapid convalescence nor the lessened risk of peritonitis, seem to outweigh the force of this primary advantage of the abdominal route in ectopic pregnancies, the more rapid and secure hæmostasis so obtained.

Inflammations of the Fallopian tubes.—From rupture to inflammations of the Fallopian tubes is a natural transition. Of these cases I have operated upon 58 with six deaths. Of all operations these are perhaps the most varied and the most difficult. One rarely finds two exactly alike. The amount of adhesions present, the difficulty of isolating, the complication of the appendix which may be greatly elongated and connected either with the right or the left tube, and numerous other factors all coincide in presenting a condition which taxes all the resources of the operator. Here, too, the difference between the two routes has been the cause of many battles; but why should any man seek to be known as a vaginal or an abdominal operator *tout seul?* Surely the wisest course must be to choose that route which in any particular case is likeliest to be followed by success. So far as my experience goes everything depends in the first place, upon the relative position of the tube with reference to the vaginal wall, and in the second, upon the acuteness or chronicity of the process. In acute cases, other things being equal, the vaginal route would appear to be much the safest; at all events for the evacuation of pus. Later enucleation and removal of the diseased tubes can be done, if required, with much more safety from above than if at any moment a weak spot which has been temporarily plugged with omentum or bowel should flood the whole pelvic peritoneum with pus while this is being separated off. It is especially in these cases that one sees the action of the omentum in executing repairs about the abdomen but unlike most tinkers its work improves with age; when just done it is not very much to be trusted. Probably, however, the greatest difficulty is found with the small intestine. As to the omentum it may be divided at a distance and so the patch be left undisturbed, but this is scarcely practicable with intestine. Theoretically a loop firmly adherent might be excised, the remaining bowel being reunited; but practically the operation for the removal of a double pyosalpinx is already long and exhausting enough for any patient. If to all the manœuvres unavoidably necessary are added those for excision of the intestine very few of these patients would survive. It is unnecessary to labour the point. It is especially in such cases that the age of the pus which almost necessarily escapes is of importance, as such pus becomes sterile if it has been long since formed. In theory all such pus should be prevented from touching the pelvic peritoneum by flat sponges placed beneath. In practice it is often impossible to place such sponges beforehand; they can only be placed in spaces already cleared, and separation of adhesions must always precede step by step their insertion. It is when the fingers are at work behind and below a tensely-filled, thin-walled large mass, where no sponge can get because there is as yet no space for it, that this dreaded escape of pus is most likely to occur. It is obvious that, if no pus is present at all, being previously drained away by a vaginal opening, the proceeding becomes infinitely safer. The following cases will illustrate the above and other points.

CASE 461.—The patient, aged 30 years, was admitted to hospital on Jan. 1st, 1902. She had suffered from sepsis after a miscarriage two years previously for which she was treated in another hospital in which she remained for four months. From that time she was in fairly good health until Sept. 29th, 1901, when she was confined of a living child. She was attended by a midwife who introduced her hand into the uterus after the birth of the child. The patient recovered slowly but being a charwoman she went to work as soon as it was possible. For 17 or 18 days before admission she felt some soreness all over the abdomen and three days later, though shivering and miserable, she was still at work, when severe pain in the lower abdomen forced her to stop and go to bed. She remained in bed for a fortnight when she was brought to hospital. Bimanual examination showed the uterus to be pushed forward in the pelvis by a large, tense, elastic mass in Douglas's pouch.

Posterior colpotomy, performed on Jan. 2nd, permitted the escape of a large amount of thin, watery, offensive pus. The temperature, which before had stood at 101° F., promptly fell to 98°. The cavity was washed out and packed with aseptic gauze which was gradually withdrawn within 48 hours. Recovery followed and the patient was sent to a convalescent home on the 31st.

CASE 309.—The patient, aged 29 years, was sent to me by Mr. Harburn of Buxton on Jan. 17th, 1898. She had been married for three years but had had no children and no miscarriages. She had always had poor health and had suffered in early life from anæmia. Six months after marriage she had suffered from "swelling of the ovary." In September, 1897, she had taken cold during a visit to Blackpool and apparently had had a rigor. Menstruation came on soon after and the blood lost was clotted and scanty. Diarrhœa followed some medicine taken and the tenesmus associated with this brought on severe pain which continued more or less until admission. Five weeks later another period came on with the discharge of dark clots. No further menstrual period had been seen. A month after the onset of this illness she began to lose flesh and strength. She also suffered from night sweats. For four months she had been almost entirely confined to bed. On examination on Jan. 17th, 1898, she was found to be much emaciated. The abdomen was slightly distended and there was a perfectly clear note on percussion everywhere. There was a firm, rounded elastic mass on each side of the uterus.

An operation was performed on Jan. 20th, the patient being placed in the lithotomy position. The cervix was isolated, the bladder was separated upwards, and the posterior fornix was opened. This incision opened into a cavity containing about two ounces of foul pus. The uterus was divided in the median line sagittally, but it was impossible to loosen and to draw down either side or to gain access to the masses above owing to the adhesions. The vagina was plugged with gauze. The patient was then placed in the Trendelenburg position and a median abdominal incision was made. A loop of small intestine was found to be adherent to the bladder and the left iliac fossa. In order to gain access to the uterus and tubes it was necessary to separate this, which, with its mesentery, completely concealed them. When this was done the divided sides of the uterus were drawn upwards and a large pus sac was seen on the left side. This was enucleated and with it half of the uterus was removed. It now became easier to deal with the right side. The right half and its tube also full of pus were taken away and the right ovary was shelled out of a mass of adhesions. This was caseous. The whole pelvic cavity was dried out with sterile mops and a gauze drain was drawn down into the vagina. The upper part of this drain was packed into the pelvis so as to isolate and drain the raw surfaces left and the abdomen was closed above. Transfusion and hypodermic injections of suprarenal extract were carried out on the table during the operation itself and she was again transfused after return to bed. The operation lasted one and three-quarter hours. Under these measures and repeated nutrient enemas containing brandy the patient rallied, the pulse returned at the wrist, and the next morning she was distinctly better. There had been free oozing from the vaginal drain but at 8 A.M. vomiting of mucus and greenish material commenced. At 2 P.M. there was sudden collapse treated by renewed subcutaneous transfusion but ending rapidly in death.

CASE 525.—The patient, aged 32 years, who had had three children but no miscarriages, was admitted on Feb. 12th, 1903. The birth of the last child had taken place six years previously. On Feb. 7th she was taken ill with pain in the hypogastrium. She continued her work, however, as a bag-maker until Feb. 10th when the pain became much worse and she had to go to bed. The pain was paroxysmal in character. The periods were regular—monthly. There was some premenstrual pain. There was also pain passing down the right leg. For several weeks before admission urination had been burning in character with the discharge of some pus per urethram. On March 20th, douching and glycerine tampons having been used since admission, urination became easier. Examination under chloroform showed a tense, elastic mass in the position of the left broad ligament. The uterus was retroflexed and the fundus was adherent in Douglas's pouch. It was not markedly enlarged.

For the operation, which was carried out on April 16th, the patient was placed in the Trendelenburg position and a median abdominal incision was made. The omentum was strongly adherent to the left Fallopian tube, which was swollen, convoluted, and closed at its fimbriated extremity. This end was adherent also to the sigmoid flexure. The mass was so firmly fixed in the pelvis and so swollen that it was necessary to begin by tying and dividing the uterine end of the tube and to separate outwards. After a great deal of difficulty this manœuvre succeeded and this tube was removed. The left ovary was left behind. On the right side the tube which had been partly concealed by the large mass of the left was also found to be swollen and convoluted. The ovary on this side was cystic. These were taken away. Many tough adhesions were found in Douglas's pouch and were separated. The question of fixing the fundus forward was considered but decided against. The abdomen was entirely closed. Flatus passed first on the 17th and a stool on the 19th; urination was naturally performed from the first. Complete recovery resulted.

CASE 560.—The patient, aged 33 years, had had no children or miscarriages. She was admitted on Dec. 26th, 1903. She had been in fairly good health until her marriage four years previously; since that time she had always been more or less ill. In August, 1902, she had been treated in another hospital for metritis. She had always been regular as to menstruation but had had leucorrhœa for many years. She was evidently in great pain when admitted and had a free purulent discharge from the os uteri. Examined bimanually, the uterus was found to be pushed to the right and fixed. There was an elastic fixed mass in the pouch of Douglas on the left side.

On Dec. 31st operation was proceeded with, the patient being put in the Trendelenburg position and a median abdominal incision being made. The omentum was found to be firmly adherent to the small intestine, the uterus, and the left tube near its uterine end. After this was tied off a somewhat dilated loop of small intestine was found to be firmly adherent to the back of the uterus and the commencement of the left tube, requiring the scissors to separate it. During this the tube gave way and some cheesy pus escaped. When the bowel was freed this rent was temporarily closed but with difficulty owing to the friable condition of the tissues. The bladder was then separated from the uterus and pressed down out of the way. The uterus itself was swollen and acutely inflamed. The right tube was short but closed at its fimbriated extremity and swollen. The right ovary was slightly cystic and some of the cysts contained pus. The left ovary might have formed part of the left abscess cavity. It was not seen as a distinct structure. Beginning on the right side the entire genital organs were removed—the tubes, ovary, uterus, cervix, and all—by the American lateral method. When all were gone there was left a very ragged looking Douglas's pouch, in which tags of adhesions and some raw surfaces were to be seen. At the back of the right broad ligament was an ulcerated opening leading into a cavity within it. From this some foul granulation material was scraped away and an opening being made into the vagina from this an iodoform gauze drain was drawn through. The ligatures upon the broad ligament and ovarian vessels were drawn through into the vagina and between them iodoform gauze, the upper end of which was left flush with the peritoneum. No attempt was made to close the pelvic peritoneum. The abdomen was then closed above. The operation lasted two and a half hours. Transfusion was required upon the table. This was repeated five hours later, not so much for shock as with an idea of diluting and washing away any toxins which might be present. The patient was nourished by nutrient enemata with brandy every four hours. For about two hours there was intense collapse. This was succeeded by intense restlessness and pain, for which morphine was given hypodermically. Flatus passed on the next day after an enema and fæces on the next night. There was some distension on the second day but this subsided after the passage of flatus. There was no rigidity. The gauze was removed on Jan. 3rd, 1904. The patient recovered perfectly with the exception of a small sinus at the site of a stitch abscess which healed rather slowly and she was sent to the convalescent home on Feb. 12th. In October, 1904, she returned with a small ventral hernia at the site of the previous stitch abscess but otherwise she was well.

CASE 614.—The patient, aged 27 years, had been married for four years. She had had no children but there had been five miscarriages. She was sent to the hospital by Mr. C.

Carruthers of Openshaw on July 15th, 1904. The last miscarriage (three months) had occurred five weeks before admission. Two rigors occurred afterwards during the second week. There was pain in the left side which steadily increased. Menstruation began at 14 years of age. It had been always regular before and after marriage except during pregnancies. On examination on July 15th the os was found to be normal and the uterus was of normal size but pushed forwards in the pelvis. A tense, elastic, rounded mass could be felt on the left side, extending from the uterus to the pelvic brim and lying behind the broad ligament. The right side of the pelvis was clear. The mass was not reachable from the vagina.

The patient was operated upon on July 18th. She was placed in the Trendelenburg position and a median abdominal section was made. The omentum was not adherent. On the left side the Fallopian tube and ovary were fused together, forming a large tubo-ovarian abscess. The uterus was reddened; the broad ligament on the left side was thickened and somewhat œdematous. The tube was much thickened at the uterine extremity. In the angle formed by the mass with the uterus the tip of the much elongated appendix was adherent. In Douglas's pouch there were many adhesions between the intestinal coils and the posterior uterine surface. The right tube was thickened, convoluted, and its fimbriated extremity closed. It was coiled around the ovary so that both had to be removed together. The uterine stumps of the tubes were touched with pure phenol and sewn to the stump of the infundibular ligament on either side. The shortened and reunited broad ligaments were then sewn over by fine silk. All clots being removed, the omentum was drawn down behind the uterus, the abdominal cavity was filled with saline solution, and the abdomen was closed by my modification of Milton's method. The patient recovered rapidly and went home on August 13th. In 1905 she returned with symptoms of acute menopause and was placed on ovarian extract, which she took in the form of tabloids for some months with very good result.

In all these cases when attacked from above immense assistance was found to be gained by the Trendelenburg position. If there were no adhesions of omentum and intestine to the pelvic organs these structures retreated out of the way towards the diaphragm; they were protected from chill by that part of the abdominal wall which was not divided; the intestines did not coil about and impede the hands of the operator, and room was left for the proper placing of protective sponges. If they were adherent the line of adhesion was made tense and prominent. As each portion was liberated it fell back and disclosed the deeper adhesions which in their turn were rendered salient. After experience of this position the surgeon would not willingly undertake one of these operations under conditions which rendered the assistance of this position unattainable. Later I shall refer to a case in which this position was gained in a private house with merely the help of ordinary articles of furniture and describe the means employed. Fortunately this particular class of case does not, as a rule, require immediate interference and there is time for the removal of the patient to a hospital or surgical home where proper tables giving this position are to be had. All operators are, I suppose, agreed as to these advantages but I have been astonished to find that many general practitioners are entirely unaware of their advisability—I might say their necessity—and are inclined to be indignant when they are recommended to send their patient to a surgical home if the house in which such patient resides is otherwise suitable for the performance of an operation.

(To be concluded.)

WATER DIVINING FOR A HOSPITAL.—At a meeting of the East Kerrier (Cornwall) district council held on August 5th it was decided to obtain at a fee of one guinea the services of a water diviner with a view to find a supply of water for the isolation hospital.

PROPOSED NEW RUSSIAN UNIVERSITY.—The Minister of Education, according to the *Slovo*, although sympathising with the movement for the establishment of a university in one of the north-western districts, will only consent, in view of the present disturbed condition of the country, to the opening with the aid of private subscriptions of separate science faculties in various towns in the area named most responding to the needs of the community.

THE CONTINUITY OF THE SEVERAL CAVITIES OF THE MIDDLE EAR,

WITH OBSERVATIONS ON THEIR DEVELOPMENT AND ON THE TREATMENT OF SEPTIC INFLAMMATION OF THE TYMPANIC CAVITY (SO-CALLED OTITIS MEDIA).[1]

BY A. H. YOUNG, M.B., C.M. EDIN., F.R.C.S. ENG.,
PROFESSOR OF ANATOMY, THE UNIVERSITY OF MANCHESTER, ETC.;

AND

W. MILLIGAN, M.D., C.M. ABERD.,
LECTURER ON DISEASES OF THE EAR, THE UNIVERSITY OF MANCHESTER, ETC.

WITH few exceptions both anatomists and otologists regard the middle ear as synonymous with the tympanum and accordingly only a single cavity—the tympanic cavity—is included in the middle ear. We hope to be able to show, however, that the middle ear includes three cavities—viz., the cavity of the mastoid antrum, the cavity of the tympanum, and the cavity of the Eustachian tube—all of which are simply modified parts of a continuous cleft intervening between the periotic capsule and the remaining parts of the temporal bone, which from the standpoint of ontogeny may be termed the primitive middle ear. Since, however, this term may lead to confusion if it is regarded from a phylogenetic standpoint, it may be better to designate it "the middle-ear cleft," and it is to be understood that it corresponds to the modified and extended inner part of the hyo-mandibular cleft of lower forms.

The primitive middle ear in man and mammals is simply a continuous cleft intervening between the periotic capsule and the united squamo-zygomatic and tympanic elements of the temporal bone (see Figs. 1 and 2). The periotic capsule forms the petrous and mastoid portions of the temporal bone and lies to the internal and posterior aspects of the middle-ear cleft; whilst the united squamo-zygomatic and tympanic elements form the outer, the anterior, and the lower boundaries of that cleft. Occasionally, although very rarely, the tympanic element joins the periotic capsule and remains distinct from the squamo-zygomatic element, but in either case it is situated on the antero-external and inferior parts of the middle ear and helps to form the corresponding walls of that cleft. The inner and outer walls of the middle ear join below without any sharp line of demarcation and a well-defined floor of the middle ear is indistinguishable, but the corresponding walls terminate above somewhat abruptly and leave a wide interval which is roofed over by the tegmen tympani. In Fig. 1 the continuity of the middle-ear cleft is seen by the removal of the tegmen tympani; the several cavities of the middle ear are distinguishable, but they are better seen when, in addition to the removal of the roof of the middle-ear cleft, the different parts of the internal ear are mapped out (see Fig. 2). The several cavities and their continuity are still better seen in the recent condition. Fig. 3 is taken from a photograph of a horizontal section cut transversely through the head of a child at birth at the level of the middle ear. Fig. 4, a special dissection of a child at birth, made by Professor Arthur Robinson, shows us from a different standpoint the same facts as seen in Fig. 3.

The preceding preparations (Figs. 1, 2, 3, and 4) show that the middle ear is a continuous cleft and although the cleft becomes modified in parts to constitute the several cavities of the middle ear the continuity of these cavities is maintained. The cavities which collectively constitute the middle ear are from within outwards: (1) the cavity of the bony part of the Eustachian tube; (2) the cavity of the tympanum; and (3) the cavity of the mastoid antrum. These several cavities are again well seen if the united squamo-zygomatic and tympanic elements are removed and the inner wall of the middle ear exposed; this is easily effected if the temporal bone is examined before the junction of the squamo-zygomatic and petro-mastoid parts has occurred. These last-named elements become joined together about the period of birth and certainly during the early part of the first year. At birth, therefore, the two parts are easily separable and the middle ear is readily exposed.

---

[1] A paper read at the summer meeting of the Otological Society of the United Kingdom held in Manchester on June 3rd, 1905.

At birth the middle-ear cleft is easily seen and on separation of the two parts which bound the cleft the chief modifications which result in the separate cavities are easily seen (see Fig. 5). At birth the middle-ear cleft is continuous, but a bulbous enlargement of the cleft which forms the tympanic cavity is interpolated between the Eustachian tube and the mastoid antrum. This bulbous enlargement is distinguishable at an earlier period and it extends both upwards and downwards. Its upward extension forms the epitympanic recess or attic. Its downward extension forms the hypotympanic recess.

In still younger preparations—e.g., about the sixth month of intra-uterine life—i.e., directly after the fusion of the centres of ossification of the periotic capsule, the different cavities of the middle ear are visible and their continuity is even more marked (see Fig. 6). In the adult the three chief cavities are, of course, distinguishable and although in consequence of a slight tilting up of the Eustachian tube and the greater extension of the tympanic cavity the continuity of these cavities is not quite so apparent, still in view of the growth and development as seen in younger forms it is obvious that the cavities are continuous and that they are simply modified parts of the primitive middle-ear cleft (Fig. 7).

As a matter of convenience in description we have more or less ignored the tympanic element and it will be sufficient to state that it usually unites with the squamo-zygomatic portion about the third month of intra-uterine life. Very exceptionally the tympanic element fails to unite with the squamo-zygomatic part. This anomaly is rarely seen, but through the kindness and courtesy of Professor Johnson Symington of Belfast we have an opportunity of exhibiting the preparations and photographs of this condition in an adult temporal bone. The squamo zygomatic part remained separate and distinct both from the tympanic plate and from the periotic capsule. It clearly demonstrates the nature of the middle ear as a cleft-like interval between the petro-mastoid and the squamo-zygomatic elements of the cranium. It is of little moment as regards the character of the middle ear whether the tympanic element is joined to one or other of the chief factors which bound the middle ear and, indeed, if the tympanic element is removed altogether the middle ear and its cavities can be easily demonstrated.

From observations on the development and character of the middle ear we think that we are justified in asserting that the middle ear includes three cavities:—(1) That of the mastoid antrum; (2) that of the tympanum; and (3) that of the Eustachian tube.

Amongst the very few authorities who do not regard the middle ear as synonymous with the tympanum and its cavity alone perhaps the most noteworthy is Politzer,[2] who states "that the middle ear, the most important part of the auditory apparatus from a pathological standpoint, is divided into: (1) the tympanic cavity; (2) the Eustachian tube; (3) the mastoid process." The mastoid process, however, is simply the outer portion or base of the periotic capsule and it lies to the inner and back part of the middle ear. It may, and does, form part of the boundary of the middle ear, but most certainly it is not an essential division of the middle ear itself. Time will not allow us to deal fully with the development of the softer tissues of the middle ear nor does it seem necessary; it may, however, be advisable to point out that the inner part of the upper and persistent portion of the *first* visceral cleft occupies the middle-ear cleft in the temporal bone previously described and that it forms the continuous mucous lining of the several cavities of the middle ear. The first visceral cleft, like all other visceral clefts, is formed by lateral outgrowths of the pharyngeal part of the foregut and corresponding in growths of the outer surface of the neck. In the case of the first visceral cleft the junction of these two parts forms the membrana tympani round about which the ring like tympanic element almost encircles the tympanic membrane. To the inner side of the tympanic membrane the first visceral cleft is lined by the hypoblast or entoderm of the primitive alimentary canal and accordingly the cavities of the middle ear are entirely lined by entodermal cells.

It is perhaps pardonable to regard the lining membrane of the mastoid antrum as being more or less of the nature of a diverticulum of the first visceral cleft, exactly as one might regard the lining membrane of the epitympanic recess or attic and the hypotympanic recess as diverticula, but even this is not borne out by a study of the earlier stages of that part of the first visceral cleft which takes part in the middle ear. The suggestion, however, that the mastoid antrum proper is a diverticulum of the tympanum is utterly and hopelessly wrong. The mastoid antrum is no more a diverticulum of the tympanic cavity than the tympanic cavity is a diverticulum of the mastoid antrum. In all probability the mastoid cells are diverticula from the mastoid antrum and it is of peculiar interest as well as of great practical importance to know that they appear at a much earlier period than is commonly supposed. Most writers affirm that the mastoid cells appear about the age of puberty. Dr. A. Buck[3] delineates well-developed air cells or pneumatic spaces in a child five years old. Sappey[4] asserted in 1867 that the air cells appear during the course of the first year and that by the second or third year they are so far developed that they form a distinctive feature. Professor Symington has lent us specimens and photographs of well-developed air cells in a nine months' fœtus and in a temporal bone of an infant one year old, and Professor Robinson writes that there are distinct but small pit-like diverticula from the mastoid antrum before birth which he takes to be the rudiments of the future air cells.

To summarise briefly the chief facts we wish to lay stress upon relating to the development of the middle ear and its cavities we desire to state:—

1. That the middle ear is simply a cleft which intervenes between the periotic capsule and the squamo-zygomatic and tympanic elements of the temporal bone. The cleft is primarily continuous and however much it may be altered in shape and modified in parts to form the cavities of the Eustachian tube, the tympanum, and the mastoid antrum, that continuity is never lost.

2. That the mastoid air cells develop at a much earlier period than is usually supposed.

With these facts in mind it occurred to us that the orthodox treatment of septic inflammatory lesions of the tympanic cavity (otitis media so-called) would require reconsideration and revision.

In a report on "The Treatment of Acute Otitis Media" presented to the French Society of Otology and Laryngology, May, 1904, by Lermoyez, Lubet-Barbon, and Moure[5] it is stated that "the tympanum and mastoid antrum communicate largely with one another ...... there are no means of isolating these chambers under normal conditions and any microbic invasion in one necessarily affects both. The result is that otitis media acuta is essentially formed by the association of an antritis and a tympanitis. From an anatomico-pathologic standpoint there is no otitis acuta without mastoiditis." As regards the treatment of otitis media the report affirms (under heading C., p. 662) "that the air douche by politzerisation cannot provoke mastoiditis because as there cannot be otitis without antritis" (and mastoiditis) "the air bulb cannot create what already exists." We are unable to accept either of these statements. Every pathologist knows quite well that localised inflammatory processes may occur even in a continuous cavity—e.g., localised peritonitis, localised pleurisy, and these examples are not limited to serous cavities alone, for we find localised inflammations in the genito-urinary, respiratory, and alimentary tracts, and one may specially mention as one of peculiar interest acute inflammation of the larynx, limited to the vocal cord of one side without any general laryngitis. We therefore venture to assert that a tympanitis does *not necessarily* involve an antritis or a mastoiditis and treatment must be influenced in view of this fact.

Inflation through the Eustachian tube goes directly to the cavity of the mastoid antrum through the tympanic cavity. In the case of a localised suppurative tympanitis, otherwise known as acute otitis media, the use of the air douche through the Eustachian tube, especially by Politzer's method, will *tend* to force septic material into the mastoid antrum and the mastoid cells. We have endeavoured to demonstrate this in the following manner. Opening up the mastoid antrum externally, as in trephining the antrum, fluid or air injected through the Eustachian tube

passes freely first through the cavity of the tympanum, then through the mastoid antrum, and the injection emerges through the external artificial orifice. A small perforation of the membrana tympani apparently makes no difference; the injection goes beyond the perforation and emerges, in the first place, through the external orifice of the antrum. This can be beautifully shown by impregnating the air with smoke; on careful observation through the perforated membrane the smoke can be seen passing through the tympanic cavity, onwards beyond the perforation to reach the antrum. It is not until the tympanic cavity and antrum are filled with the smoke-laden air that it emerges through the orifice of the perforated membrane.

This experiment we have done repeatedly, both by means of a membrana tympani perforated artificially and one perforated by inflammatory disease; in every case the smoke-laden air emerges, in the first place, through the external opening of the mastoid antrum and never, primarily, through the perforated membrana tympani. After repeated experiments on the same ear the smoke appears almost simultaneously through both the openings—viz., that of the perforated tympanic membrane and the external opening of the mastoid antrum. This is explained by the fact that the whole of the middle ear is filled with smoke after such repeated experiments. These experiments, we think, conclusively prove that when air or water is inflated it is first forced into the mastoid antrum irrespectively of whether the membrana tympani is perforated or not. We suggest that it would then be forced into the mastoid cells if formed and the fact that these cells are formed early means that there can be no distinction as regards treatment in the child and in the adult.

The conclusions to be derived from these experiments are open to the criticism that an external opening of the mastoid antrum is not present until operative measures have been undertaken. The presence of an external orifice will undoubtedly modify greatly the passage of injected air or fluid through the antral cavity but this modification is merely in the direction of increased quantity and increased facility of transit. The point which we seek to emphasise is that even when the external aperture is wanting there still exists a tendency for injected air or fluid to pass in the same direction. Beyond this one cannot go. Clinical experience teaches us that the disastrous results which follow the passage of septic material into the antrum are not invariable after politzerisation but we are convinced that from the anatomical arrangement of the parts they are by no means impossible.

Politzer states,[6] on the authority of Michael,[7] that "the view that in perforative inflammation of the middle ear purulent secretion is driven into the mastoid cells by the air douche has been disproved" and that Michael had "demonstrated experimentally that the secretion is always expelled into the external meatus," presumably through the perforated membrane. We think that our experiment proves that Michael's view cannot be substantiated. Our contention, therefore, is that in acute septic disease of the middle ear inflation should not be employed. If, however, for any special reason inflation be deemed advisable the Eustachian catheter should be passed and air driven into the cavum tympani with great care and gentleness. We believe that in every case of septic middle-ear disease the first and primary requirement from the anatomical, pathological, and surgical point of view is free and unimpeded drainage. To carry this principle into effect a free incision of the membrana tympani is essential and it is equally essential that the incision be kept open in its whole length by re-incision where necessary or by the actual removal of a triangular wedge of the membrana tympani itself. Furthermore, we believe that aspiration of the contents of the cavity of the middle ear by means of Siegle's speculum or Delstanche's raréfacteur is a therapeutic measure of the first importance, especially when combined with adequate drainage.

DESCRIPTION OF THE FIGURES.

We desire to express our indebtedness to Professor Symington, to Professor Robinson, and to Professor Peter Thompson (King's College, London) for their kindness in lending us many specimens and photographs.

All our figures were reproduced by photographs taken from actual specimens and of these Figs. 1, 4, and 5 were taken from specimens lent to us by Professor Thompson from the collection in the anatomical department at the Middlesex Hospital. Fig. 6 is taken from a photograph of a special dissection made by Professor Robinson. The remaining figures are taken from preparations in our own collection.

FIG. 1.—Right temporal bone of a child, aged four years, showing the "middle-ear cleft" after removal of its roof, the tegmen tympani.

FIG. 2.—Right temporal bone of a child, aged four years. The tegmen tympani has been removed and the parts of the internal ear have been mapped out. The specimen shows the middle ear and its several cavities.

FIG. 3.—Horizontal section of head of a child at birth made by Professor Thompson. The section is cut transversely through the head at the level of the middle ear and shows the continuous cavities of the Eustachian tube, the tympanum, and the mastoid antrum—i.e., the cavities included in the middle ear.

FIG. 4.—Dissection showing the middle ear and its cavities and the relation of the middle ear to the external auditory meatus in a child at birth. The dissection was made by sagittal and coronal sections, removing a wedge-like portion of the face until the middle ear cleft and the external auditory meatus were exposed. It shows from a different standpoint the points seen on Fig. 3, but owing to the oblique position of the specimen it does not show the whole of the mastoid antrum.

FIG. 5.—Right temporal bone at birth. The squamo zygomatic element has been separated and the inner wall of the middle ear is exposed; the several cavities included in that cleft are well seen.

FIG. 6.—Right temporal bone of a six months' fœtus. Similar preparation to that shown on Fig. 5 but at a much younger stage. It shows all the cavities of the middle ear but their continuity is more marked than at a later stage. Further, it shows indications of the commencing mastoid cells.

FIG. 7.—The middle ear and its cavities in the adult.

GENERAL STAPHYLOCOCCIC INFECTION TREATMENT BY ANTISTAPHYLOCOCCIC SERUM AND HETOL; DEATH.

BY E. F. MAYNARD, M.D. EDIN., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN, SUSSEX COUNTY HOSPITAL;
AND
F. G. BUSHNELL, M.D. LOND.,
PATHOLOGIST (STEPHEN RALLI MEMORIAL), SUSSEX COUNTY HOSPITAL
LATE HONORARY PATHOLOGIST, SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH, ETC.

BUT for the fact that a post-mortem examination was made in this case it would have been classed as one of vegetative endocarditis. That this would have been an incorrect classification will appear from the post-mortem report. It has seemed to us that the case is an instructive one and worthy of publication, if only by reason of the negative results of the treatment followed, a treatment based on the supposition that it was a case of infective endocarditis and therefore probably of a mixed infection, as pointed out by Dr. Cyril Ogle. Though the clinical course of the case strongly supported such a diagnosis the onset was in no wise suggestive of this disease.

The patient was a man, aged 23 years, a painter, and beyond the fact that there was an account of rheumatic fever at the age of 13 years there was nothing worthy of note in his previous history. He was well until the morning of March 19th, 1904, when at 11 o'clock he had a sudden pain in the "stomach" followed by shivering. He shivered off and on until the evening when he became feverish. The next day he was feverish but had no pain and the following night he was "light-headed." On the 21st he came to the out-patient department with the above history. His temperature was then 101° F. and the spleen was easily felt below the costal margin. He was admitted. For the following notes we are indebted to Mr. J. B. Stevens, the house physician. The patient was flushed. His temperature was 102°. There were sores about both external nares and a semi-purulent discharge which had existed "for some time." The tongue was red and dry. The pharynx was normal. The abdomen was slightly distended but moved freely with respiration. The spleen was enlarged and easily felt. The liver was not enlarged and there was no local or general tenderness. The lungs were healthy and there were no adventitious sounds. The pulse was dicrotic (96). There was a soft apical systolic murmur conducted for a short distance towards the axilla; it was not suggestive of valvular disease of 13 years' standing. There was no evidence or history of any genito-urinary disease. The urine was alkaline, of specific gravity 1018, and phosphatic; there was no albumin. The hands and tongue were tremulous. On March 22nd the temperature had been up to 104° in the morning and night and on the morning of the 23rd and it had not been lower than 100·4° since admission. Tepid sponging was employed when it was above 103°. The second heart sound on the 23rd was reduplicated in the aortic and pulmonary areas. The reduplication was louder and more distinct—in fact, quite sharp—to the left of the sternum. There was no diastolic murmur. The air entry at the right apex was poor. The spleen was smaller and was now only just palpable. The general condition remained unaltered. Dr. Bushnell took blood from the left basilic vein with the usual aseptic precautions as regards syringe, needle, and skin; he also took a culture of the nasal discharge. On the 24th the second sound at the base was rumbling in character. The abdomen was more distended, the spleen was not felt, and the highest temperature reached during the past 24 hours was 104° and the lowest was 102·6°. On the 25th there was a distinct diastolic murmur in the pulmonary area conducted down the left side of the sternum; it was not heard in the aortic area. There was no increase of cardiac dulness. Much pain was present in the left side of the chest in the morning and a to-and-fro pleural rub was heard in the lower part of the left axilla and just below the heart's apex beat. On ophthalmoscopic examination the discs were seen to be normal. The pathologist reported that as regards the nasal discharge "two colonies of staphylococcus albus have grown" and as regards the blood "ten c.c. of blood from left median basilic vein sown on agar and gelatin tubes gave a growth in 48 hours of staphylococcus (Gram staining, non-capsulated), probably pyogenes albus; the appearance of short chains in scanty numbers suggests possibility of mixed infection; if plating had been practicable streptococci might have been isolated; no pneumo- or gono-cocci isolated." On the receipt of this report, and considering the possibility of a mixed infection, ten cubic centimetres of polyvalent antistreptococcic serum were given at 4 P.M. A differential blood count showed 80 per cent. of polymorphonuclears. On the 26th the diastolic murmur was louder and there was also a systolic murmur at the base. There was a trace of albumin in the urine which was now acid. The temperature had been no higher than 103·6° and as low as 101·2° during the 24 hours. Another ten cubic centimetres of antistreptococcic serum were given. On the 27th the pleural rub was more extensive. The pathologist reported: "Leucocyte count, 9500—85·6 per cent. polymorphs." In the afternoon the patient had a rigor and the temperature rose to 104°; ten cubic centimetres of antistaphylococcic serum were given. On the 28th the abdomen was more distended and considerable subsultus was present. The temperature was higher in the evening. Ten cubic centimetres of antistaphylococcic serum were given and one-third of a grain of hetol intravenously with the object of establishing a more marked leucocytosis. On the night of the 28th the patient was wildly delirious and in the early morning of the 29th the temperature dropped to 97° and he slept. In the morning his mental condition was quite clear and he said that he felt better. The diastolic murmur was best heard at the aortic cartilage. Ten cubic centimetres of antistaphylococcic serum were given at 6 P.M., when the temperature was up to 103° again, this being followed by ten cubic centimetres of normal horse serum at 8 30 P.M. The temperature at 10 P.M. was 104·4.° The pathologist reported: "There are 14,700 leucocytes per c.mm. blood." On the 30th percussion resonance over both bases was impaired; there was no true bronchial breathing. The patient was coughing up a good deal of foul, bloody, frothy sputum. Ten cubic centimetres of normal horse serum were repeated and one grain of hetol was given intravenously at 3.30 P.M. The leucocyte count five hours later was 14,200. On the 31st the respiratory murmur was diminished and the voice sounds were distant over the left lower lobe; there was also impaired percussion resonance. The temperature was gradually declining; the general tremor was increasing, however. The tongue was dry and the blood-stained frothy expectoration was troublesome to the patient. Normal horse serum and hetol were again given. On April 1st, the asthenic condition gradually increased and he died at 10 A.M. About an hour after death, the heart having been seared, a sterilised needle was inserted into the right ventricle and four broth tubes were inoculated with the blood withdrawn; all these tubes developed pure staphylococcus. The pathologist reports: "Films and cultures of sputum show staphylococcus and organism, probably B. coli communis. Spleen (culture in broth made with usual aseptic precautions, post mortem) shows bacillus, probably coli communis, and staphylococcus. Urethra (culture in broth, post mortem) discharge shows bacillus, probably coli communis. Blood (ante mortem) culture on gelatin developed, and was pure staphylococcus, liquefying gelatin freely."

At the necropsy 48 hours after death numerous septic infarcts were found in both lungs with broncho-pneumonia; septic infarcts were also found in both kidneys. As regards the heart there was recent and extremely slight endocarditis of the pulmonary cusps. There were no definite vegetations, merely a roughening presenting a hirsute appearance; there was no endocardial injection. A firm fibrous nodule was found attached to one of the chordæ tendineæ of the tricuspid valve. Both mitral and aortic valves were healthy. The spleen was two or three times the normal size, soft and friable; it contained no infarcts. The sphenoidal and ethmoidal cells were opened and found to be healthy.

Remarks by Dr. MAYNARD.—The chief feature of note in the treatment of the case was the absolute failure of the various sera to bring about any improvement. The infection would appear to have been one of staphylococcus albus only and possibly the failure was due to the fact that there is no antiserum made for this organism; on the other hand, it may be that a sufficiency of antistaphylococcic serum was not given and that it was not given early enough in the disease. After perusing the very valuable lectures of Mr. L. S. Dudgeon and Mr. P. W. G. Sargent, recently published,[1] one would suppose that the white staphylococcus was almost a benign organism, at all events as regards the peritoneum, and possibly this is so, more particularly as compared with other peritoneal pyogenic organisms; that it may, however, exist in a very highly virulent form also is shown by this case in which it was cultivated both ante and post mortem from the blood and was apparently *per se* the cause of death. Normal horse serum was used solely on account of its reported efficacy in a case of septicæmia mentioned to us and in lieu of any better possible remedy. The point of entry of infection was probably the nose, as, though a most thorough search for other entries was made, none was found.

Remarks by Dr. BUSHNELL.—There have been several fatal cases of septicæmia at the Sussex County Hospital due to infection by staphylo-, strepto-, and pneumo-coccus in which the path of entry of the micro-organism could not be precisely demonstrated; in these the serous sacs were more especially affected, also the meninges, and in the case now reported the lungs contained numerous foci of suppuration. In this case the presence of the staphylococcus in the blood ante and post mortem, in the nasal discharge and in the sputum during life, and in the spleen, lungs, and kidneys after death, is evidence of the infection being staphylococcic; further, there were no pneumo- or gono-cocci in the blood cultures, nor streptococci in plate cultures. This with the absence of bacilli and the presence of staphylococci in numerous sections of the viscera prepared by Weigert, Gram, and Löffler's methylene blue methods show the infection to be staphylococcal. There is strong probability, too, that the respiratory tract was the path of entry. The lack of success in the treatment by antiserum may lie in the fact pointed out by Pröscher,[2] that variations in races of staphylococci occur; thus it is important that the strain from which the serum is prepared should be identical with that causing the suppuration. The use of a vaccine of sterilised staphylococcal cultures, even if it were administered at the periods recommended by Dr. A. E. Wright[3] and after estimating the phagocytic power of the blood by Leishman's method,[4] would not be likely to prove of any therapeutic service in such an acute case as this. The absence of leucocytosis, in the presence of such grave infection and after the exhibition of hetol, would be associated with diminished phagocytic and bactericidal protective fluids in the blood. Success in treatment of such conditions appears to be in the direction of stimulating or supplementing such bodies, whether "immune body" or "alexin," and phagocytosis, by direct or indirect measures. The necessity for the prevention of such illnesses by means of general hygienic measures and special precautions against infection is not apparently yet recognised by the public.

ELEMENTARY STATE SCHOOLS AND THE SPREAD OF CONTAGIOUS DISEASES OF THE SKIN.[1]

BY P. S. ABRAHAM, M.D. DUB., F.R.C.S. IREL.,
SURGEON TO THE HOSPITAL FOR DISEASES OF THE SKIN, BLACKFRIARS, AND DERMATOLOGIST TO THE WEST LONDON HOSPITAL.

I DESIRE again to call attention to a matter which is *manifestly one of great importance to the* public as well as to the medical practitioner. In a joint paper by Dr. Alfred Eddowes and myself read in the Section of Preventive Medicine of the congress of this institute which was held at King's College, London, in 1894, it was pointed out that "now that school attendance is compulsory and that the clean and well-cared-for children of respectable families living in poor neighbourhoods often have to associate with those of the dirtiest, most careless, and most diseased classes of the community, it seems to us a moral duty that all reasonable precautions be insisted on (and carried out) by the authorities in order to minimise the risk of infection from the diseased to the healthy. ...... Numerous instances have come to our knowledge in which not only has a skin disease been contracted in a board school but it has been carried home by the child and passed on to the previously healthy brothers and sisters."

A continued and very extensive experience of the treatment of diseases of the skin at two large London hospitals leads me thoroughly to endorse those remarks made 11 years ago; and I have no hesitation in now saying that we must regard the elementary State schools in London as largely responsible for the spread of such contagious diseases as ringworm, pediculosis, scabies, impetigo, &c., and of many perhaps more grave affections which may be their sequelæ, not only directly among the children of the poorer classes but indirectly among those of the well-to-do. The facts appear to be so obvious that it is astonishing that the authorities have not sufficiently realised their responsibilities in this connexion and have not adopted more efficient measures for preventing the contamination of healthy children. I do not deny that the late School Board and the present education department of the London County Council have given, or are now giving, some practical attention to the subject, but I maintain that the methods and precautions hitherto adopted by those authorities have been, to say the least, very defective and inadequate. It seems to me that one of their greatest mistakes is their attempt to shift the responsibility upon the wrong shoulders; they have not themselves had the children properly inspected, but they have put the onus of investigating such cases upon others, the result being that numbers of diseased children are still attending the schools and infecting other children.

Under the present system if a poor child acquires ringworm, for instance, he or she may attend a school for a considerable period without anyone being any the wiser and be all the time quietly disseminating the affection. When it is a typical case and something wrong is at last observed by the teacher the child is sent home and the parents are told that they must get an official form filled up by a medical man. An instance in illustration of this has just occurred at Blackfriars. A mother brought two children with well advanced ringworm and was asked how long they had been affected. She replied that "she observed their heads 'scurfy' about two months ago and then got some ointment for them from a chemist." Had they been attending school? "Yes, until this morning, when they were sent home by the teacher." She did not know until that day that they had ringworm. It will not be surprising if other cases crop up from the same school. If the parents are very poor they may not be able to afford the fees of a general practitioner and their usual course is to bring the child to a hospital—often with a cool message from the elementary school teacher or inspector that the hospital medical officer must fill up the official school form. It has been my invariable practice to decline to do anything of the sort, and I venture to think that if all medical men in my position adopted the same course the school authorities would have been long before this brought to their senses and have ceased from attempting to "sponge" upon the honorary officers of a hospital and from trying to get the latter to do work which is really on behalf of the school and, not for the individual benefit of the poor little patient. I do not wish to be misunderstood: if a child is brought to the hospital really ill or suffering from a complaint which would be made worse by going to school—i.e., if attendance at school would be detrimental to the child's health—I readily give a certificate (our own hospital one) to that effect. But as regards ringworm and some of the other cases to which I have alluded, it is for the sake of the school—in view of the risk of infecting other children—that the child should not attend. Children so affected may be, and usually are, perfectly well in every other respect; school is good for them; and the only reason why they should not attend is that they may, and probably will, communicate the disease to others.

I think it will be generally agreed that it should be the bounden duty of the education department to protect healthy and clean children from being infected at school with the above-mentioned loathsome diseases. I may even go so far as to say that should it be proved that a child has contracted such a disease at the school the necessary treatment for cure as well as the preliminary investigation ought to be at the expense of the department. I have often wondered indeed that some indignant and justly aggrieved parent has not brought an action at law and claimed damages for the injury done by the introduction of such a disease as ringworm into his house through being forced to send his child to a school in which there are cases of the kind.

What is the remedy? Obviously the most important and essential prophylactic measure would be the frequent systematic and periodical examination of all children attending the Government schools by competent medical officers especially engaged for that purpose by the department. This was recommended many years ago but was evidently not thought worth adopting by the late School Board probably on the ground of expense; the institution of continuation schools and the other developments—ornamental or otherwise—of Mr. Forster's original Act were no doubt considered of greater importance and more worthy of the ratepayer's money. I understand that the London County Council is actually going at last to increase the at present ridiculously inadequate medical staff of its education department and to employ a number of medical men to look more closely after medical matters in the London schools—it is to be hoped for the benefit of the children who have to attend the State schools. This, at any rate, is a satisfactory although tardy move in the right direction. That august body, however, still seems to think that it has the right to demand the gratuitous services of hospital medical officers, as is evidenced by a letter dated July 13th, 1905, now before me, addressed to the secretary of one of the hospitals to which I am attached.

It seems to me high time that medical men should make a stand against the system hitherto in vogue in the department and that the public should know the risks their children are being forced to incur through the lack of adequate medical supervision of the elementary schools.

Henrietta street, W.

THE STAINING REACTIONS OF THE SPIROCHÆTÆ FOUND IN SYPHILITIC LESIONS.

BY LEONARD S. DUDGEON, M.R.C.P. LOND.,
BACTERIOLOGIST TO ST. THOMAS'S HOSPITAL AND JOINT LECTURER O GENERAL PATHOLOGY IN THE MEDICAL SCHOOL.

(*Preliminary Note.*)

Dr. Schaudinn and Dr. Hoffmann have pointed out the extreme difficulty which they have experienced in staining the spirochætes which they have recently shown to be present in various syphilitic lesions. These authorities have, therefore, recommended a special stain which they have found to be the only one that has yielded positive results. It is for this reason that I wish to bring forward the results which I have recently obtained by employing a slight modification in the strength and method of using Leishman's stain.

---

[1] A paper read at the London Congress of the Royal Institute of Public Health on July 20th, 1905.

A patient suffering from syphilis recently attended the out-patient department of St. Thomas's Hospital. I succeeded in obtaining a large quantity of fluid from a condyloma situated in the region of the anus by using severe local pressure. A number of cover-slip preparations of the exudate were made and these were stained as follows. I used a sample of Leishman's stain, such as I employ for staining bacteria. 1. A few drops of a 1 per cent. solution of Leishman's powder (Grübler) in absolute methylic alcohol (Kahlbaum's) were poured on to the surface of the film preparation, just sufficient to cover completely the whole of the cover-slip. This was allowed to fix the specimen and to stain it for 30 minutes. 2. Double the volume of distilled water as to stain was now run on to the surface of the cover-slip and the stain and water were carefully mixed. The staining was further continued for five minutes. 3. The diluted stain was poured off and distilled water was run on the cover slip and allowed to remain on for one minute. 4. Surplus stain and any precipitate were now removed by squirting some distilled water on to the film from a pipette. 5. The film was then dried with cigarette paper and mounted in Canada balsam.

I obtained excellent preparations of the organism by means of the above process and was able to observe a large number of spirochætæ in most of the film preparations; the organisms could be recognised quite distinctly, however, by staining according to Leishman's own method. Its morphological characteristics corresponded to the type described by Dr. Schaudinn and Dr. Hoffmann as the spirochæta pallida. It was found to be extremely delicate, but perhaps the most noticeable point concerning this organism is the typical corkscrew arrangement; in some cases from 10 to 15 spiral turns were seen. Each spiral was also found to be defined very sharply. Some spirochætæ, however, were thicker, showed polar staining with Leishman's stain, and did not have the typical corkscrew characters of the spirochæta pallida. This type probably belongs to that described by the above-mentioned authorities as the spirochæta refringens.

It is quite possible that with a little trouble still better results can be obtained with Leishman's stain, which has already been shown to be one of the most valuable stains in use at the present day.

Note.—Since the above account was written further results have been obtained with film preparations of the exudate from "mucous patches" in a case of secondary syphilis, under the care of Mr. P. W. G. Sargent.

St. Thomas's Hospital, S.E.

TWO CASES OF ADDISON'S DISEASE AND THE EFFECT OF THE ADMINISTRATION OF SUPRARENAL EXTRACT.[1]

BY A. GORDON GULLAN, M.D. LOND., M.R.C.P. LOND., F.R.C.S. ENG.,

LECTURER ON CLINICAL MEDICINE, UNIVERSITY OF LIVERPOOL; PHYSICIAN TO THE LIVERPOOL STANLEY HOSPITAL.

As the effect of the administration of suprarenal extract in the treatment of Addison's disease is still *sub judice* I think that the results obtained by the administration of this drug in two cases of that disease which have recently been under my care will be of interest.

CASE 1.—The patient, aged 18 years, was admitted into the Stanley Hospital on Sept. 7th, 1903, complaining of pains in the epigastrium, vomiting, and weakness. His pulse was extremely small and his face was sallow. There was no history of phthisis or tubercle in his family. The lad stated that he had always been healthy up to the time of the present illness, which began, according to him, two months prior to admission, when he was troubled with severe aching pains in the epigastrium following food but these were relieved by vomiting after each meal. He said that he had lost flesh during his illness and had become very weak; he also noticed that "his skin was yellow."

On admission the patient was found to be a thin but well-developed youth; his face and hands were cold and livid and the temperature was subnormal at from 97° to 98° F. There was a large amount of pigmentation of the skin over the body, but it was especially marked in certain regions—namely, *in the exposed parts*, the neck as far as the collar where it ended abruptly, and the back of the forearms where it gradually shaded off; *in the normal sites* there was deep pigmentation of the axillæ, the nipples, the penis, and the scrotum; and *in the parts exposed to pressure*, the lumbar region of the back, especially the lumbar spines, about the knees, the soles of the feet, and also in two scars on the back of the left forearm. The pigmentation was of a yellowish-brown or copper tint, shading in some regions to a dark brown and reaching a maximum in some small black pigmented spots scattered about the chin, the lips, the back, and the ankles. There was also some copper-coloured mottling on the mucous membrane of the cheeks and gums. There was tenderness in the epigastrium and left hypochondrium on deep pressure, and a distinctly tender spot was found over the eleventh and twelfth ribs posteriorly on each side (three inches from the spine on the right and two and a half inches on the left). The pulse was 80 per minute, extremely small and of very low tension but regular. At no time could a sphygmographic tracing be obtained. The cardiac impulse was absent. There was no superficial dulness and the deep heart dulness only extended three inches to the left. The heart sounds were clear at all areas but distant. Liver dulness was four inches in the nipple line. Splenic dulness was normal. The patient had no cough and the respirations were 20 per minute, otherwise normal. The urine was acid, scanty, high-coloured, contained urates on standing, and a trace of albumin sometimes. The quantity of urea was relatively greatly increased. The muscular system was flabby but there was not much wasting.

Our first care was to stop the persistent vomiting, so the patient was placed on a very light diet and ten grains of bismuth carbonate were given just before food, with the desired effect for a time. On Sept. 14th extract of suprarenal in five-grain doses was given thrice daily and this was increased to ten grains a few days later. On Oct. 2nd the suprarenal extract was increased to 15 grains and the patient had improved. He had no pain and had not been sick for a week and his pulse was a little stronger. This improvement was maintained until the 19th but he was steadily losing weight, about two pounds per week, and the pigmentation in the mouth was more marked. On that date the vomiting returned with all its severity; he complained of acute pain in the abdomen and in both lumbar regions, pressure under the last rib on each side causing him to jump and cry out. The pain was so intense on the 22nd that he lay curled up in bed groaning; he was very sick and all medicines had to be stopped; hypodermic injections of morphine were given to relieve the pain, and some brandy. The muscular weakness was most pronounced at this time and the deep cardiac dulness was found to have further diminished. The patient gradually became semi-conscious and died on Oct. 25th.

The post-mortem examination was made on the same day and the report is briefly as follows. The body was extremely emaciated, there being marked pigmentation of the skin as noted during life. The lungs were healthy and there was no evidence of tubercle recent or old. The heart was small, the muscle substance being atrophied, pale, and friable; the valves were healthy. The stomach was large and somewhat congested; the bowels were healthy. There was considerable matting of chronic inflammatory tissue in front of the aorta round the cœliac axis and affecting the cœliac plexus, the semilunar ganglia, the terminations of the greater and lesser splanchnic nerves, and extending outward to the suprarenal bodies. Both suprarenal glands were very much enlarged, nodular on the surface, and hard; on section both glands showed numerous caseous and fibrous nodules varying in size from five to 15 millimetres in diameter.

CASE 2.—The patient was a married woman, aged 32 years. It was ascertained that one brother had died from pulmonary tuberculosis. The patient had had eight children, six of whom were alive. With regard to the other two children, one had died from meningitis and the other from diarrhœa. The present illness began two years previously when she was, she stated, getting thin, low spirited, and continually fainting; she also had had great pain in both lumbar regions, particularly in the left. As she had a severe attack of vomiting in January, 1904, she applied to the Stanley Hospital and was admitted. She was then noticed to have slight bronzing of the lower half of the face and neck. Her pulse was very small and easily compressible, and she had marked tenderness over both suprarenal bodies. There was general lassitude and her temperature was frequently subnormal, occasionally falling to 97° F. The tongue was coated, the bowels were rather constipated, and vomiting was troublesome. She was placed on light diet and calcium chloride and tincture of nux vomica were prescribed. After three weeks she became an out-patient and has remained so ever since, having been re-admitted, however, on two occasions (i.e., in March and August, 1904). Up to the latter date her condition became worse, the pigmentation was more marked on the face and neck, and also appeared on the backs of the forearms and on the hard palate; she was also more subject to syncopal attacks. On August 5th she was ordered five grains of suprarenal extract four times a day, and this was increased to ten grains and then to 20 grains thrice daily. This treatment was continued up to Dec. 9th with considerable benefit; she lost her lassitude to a great extent, had no fainting attack, her pulse was stronger, she vomited much less frequently, and the tenderness over the suprarenals was not so marked. She also gained in weight. On Dec. 9th she was confined and had a normal and easy labour, the child being healthy. She was then absent from the out-patient department for three weeks and consequently the suprarenal extract was omitted for that time and it is an interesting fact that the symptoms from which she had been free—i.e., fainting, vomiting, and general lassitude—all gradually returned. On Jan. 2nd, 1905, the suprarenal extract was recommenced and the above symptoms steadily abated. She has been taking from 20 to 30 grains of the extract regularly up to the present time with great benefit. On another occasion, however, in April, she had a mild attack of bronchitis when it was omitted for a short period whilst some expectorant treatment was given and then her former symptoms returned and the pigmentation increased. These diminished when she took the extract again. She is now in fair health, has gained in weight, and only on occasions is troubled by vomiting or a syncopal attack, but we notice that if she omits the suprarenal extract for only a few days through not coming to the hospital her pulse is always much weaker and her symptoms aggravated. This case, in the benefit she has derived from suprarenal extract given by the mouth, agrees with the two cases reported by Dr. G. Oliver[2] (though the bronzing has not improved to the extent which appears to have been apparent in his second case), and also with that recorded by Dr. H. D. Rolleston[3] in his admirable Goulstonian lectures. It also illustrates how the treatment must be continued, as laid down by Dr. Rolleston[4] and also that the suprarenal extract must be given in large doses. Dr. E. Lloyd Jones records a case of Addison's disease[5] which was cured by taking 12 tabloids per diem—my patient is taking 18 tabloids per diem.

---

[1] Notes on these cases were read by Dr. Gullan at the Liverpool Medical Institution on Feb. 16th, 1905, when he also showed the second patient.

The special points of interest in these cases are the following: 1. The severity and rapid progress of the disease in Case 1, though the lesion was that of chronic tuberculosis of the suprarenal bodies plus secondary inflammation of the neighbouring sympathetic, and the little benefit derived from the extract. 2. The chronicity of the symptoms in Case 2 and the considerable benefit derived from the suprarenal extract, so that she even easily stood the strain of pregnancy and parturition. These cases certainly lead me to support Dr. Byrom Bramwell's view[6] that those cases which improve on this form of treatment may be due to adrenal inadequacy alone and the remainder are due to an additional lesion (I should like to word it a secondary lesion) of the neighbouring sympathetic. This was the condition in Case 1. But I cannot agree with Dr. Bramwell's suggestion that all those cases which improve have a non-tuberculous lesion (though some of them may have, as the one recorded by him), for it seems quite logical that in the early stage of Addison's disease when of an undoubtedly tuberculous nature (and personally I have not yet seen a case post mortem in which the condition was not of a chronic tuberculous nature) the disorder starts in the adrenal body and may lead to inadequacy of that body before the sympathetic plexuses are involved. At such a stage I believe treatment by suprarenal extract would be most beneficial and if combined with good wholesome diet, fresh air, &c., the disease may be checked or cured; but then if there remains as a result sclerosis of the adrenal bodies the suprarenal extract would have to be continued to supply the internal secretion of the organ probably for the rest of the patient's life. Hence the great importance of early diagnosis and an early trial of this form of treatment in Addison's disease.

MARGATE COTTAGE HOSPITAL.

A CASE OF RUPTURED URETHRA AND EXTRAVASATION OF URINE OF FOUR DAYS' STANDING.

(Under the care of Mr. W. GREENWOOD SUTCLIFFE.)

THE accident occurred during a storm in the Bay of Biscay on March 8th of this year; the patient, a Swedish sailor, 35 years of age, was thrown violently, his perineum struck a projecting beam, and he was picked up practically unconscious. The steamer, a homeward-bound eastern trader, carried no surgeon, and beyond getting the man to his bunk the captain could do little for him. A large swelling rapidly developed in the perineum, the scrotum, and the cellular tissue of the penis; there was inability to pass urine and the condition of the patient on his arrival at Margate on March 12th, four days after the injury, was one of extreme exhaustion and collapse. Several attempts at landing him had been made during the voyage up Channel but the weather was too severe to permit it and even here the transfer of the patient was only effected by means of the lifeboat. Dr. C J. Harnett, who had previously reached the steamer in a smaller boat, superintended the removal and on admission to the hospital the case came under the care of Mr. Sutcliffe. The bladder was found to be distended above the umbilicus, the skin over the left side of the perineum and the inner side of the left thigh was black and gangrenous, and the scrotum and penis were greatly swollen and black but firm and not crackling to the touch. The right side of the perineum was only gangrenous for about an inch outwards to the thigh and the skin of the right thigh was unaffected. The skin over the left thigh outside the area of the gangrenous patch, itself at least six inches square, was of a dusky red hue and the whole thigh down to the knee was tense and swollen. The urethra had obviously been ruptured in the membranous portion as no extravasation had spread forwards into the scrotal tissues or on to the abdomen; the posterior layer of the triangular ligament had probably itself been torn, as most of the urine had found a way into the left ischio-rectal fossa near the rectum and anus and into the subcutaneous tissue of the left thigh. The patient was anæsthetised and put in the lithotomy position; the perineum was incised freely in the middle line and large quantities of clot and infiltrated débris were cleared away; a director was then passed through the rent in the urethra into the bladder and some 50 or more ounces of clear urine were evacuated. Free incisions were then made over the infiltrated area, the gangrenous skin over the inner side of the thigh was cut away, and a large rubber catheter was tied in the bladder through the perineal wound.

Recovery began at once, the patient, a man of fine physique, rapidly passing out of danger. The separation of sloughs was assisted by soaking the patient in a hot bath for several hours daily and the catheter was retained in the perineum for a fortnight before an attempt was made to re-establish the normal urethra. Then a large steel sound was easily passed down the urethra into the bladder and the catheter was removed from the rapidly contracting perineal aperture. Control over the bladder being soon re-established and the patency of the urethral channel secured by the passage of sounds at intervals of a few days, the patient soon began to pass his urine in increasing quantities through the natural route. The perineal opening gradually contracted to a pin-point aperture and the denuded surfaces soon covered themselves with granulation tissue and healed with amazing quickness. The patient left the hospital soundly healed on June 3rd, a No. 12 steel sound passing easily into the bladder the day before his departure. Beyond a single rigor after the first passage of the sound he had no bad symptoms from first to last and with that exception his temperature was below 100°F. throughout.

[5] Brit. Med. Jour., 1895, vol. ii., p. 483.

[6] Brit. Med. Jour., 1897, vol. i., p. 71.

Remarks by Mr. SUTCLIFFE.—The case is interesting as showing remarkable recuperative powers after a severe injury unavoidably left untreated for several days and as affording a contrast to those instances of extravasation due to stricture or peri-urethral abscess when the urine is septic; in such cases recovery can hardly be expected after 48 hours' soaking of the subcutaneous tissues in ammoniacal urine. In two cases of this injury which have come under my care within a few hours of the accidents I have passed a catheter through the rent at the first operation, but here with a large sloughing mass of cellular tissue the only course was to drain directly through the perineum, and though the urine itself had not spread upwards both the scrotum and penis were greatly swollen with infiltrated blood; indeed, the discolouration had hardly disappeared from the skin of the penis when the patient was discharged.

Reviews and Notices of Books.

A System of Clinical Medicine, dealing with the Diagnosis, Prognosis, and Treatment of Disease, for Students and Practitioners. By THOMAS D. SAVILL, M.D. Lond., Physician to the West-End Hospital for Diseases of the Nervous System; Physician to St. John's Hospital for Diseases of the Skin, London; formerly Medical Superintendent of the Paddington Infirmary. Vol. II.: Certain General Disorders; Diseases of the Skin and the Nervous System. London: J. and A. Churchill. 1905. Pp. 444. Price 8s. 6d.

IN a review of the first volume of this work, which appeared in THE LANCET of April 25th, 1903, p. 1174, we expressed the high opinion we had formed of the manner in which Dr. Savill had carried out the task which he had set himself. A perusal of the recent volume assures us that on the whole the same high standard has been maintained which was manifest in its predecessor. We then explained that Dr. Savill had approached the subject of clinical medicine from the standpoint of symptomatolgy. This method of procedure is well illustrated by the heading of the first chapter in the volume now under consideration, which runs, "General Debility, Pallor, and Emaciation." In this group might naturally be placed a very large number of varying conditions. Dr. Savill explains, however, that he is merely concerned with those diseases in which a feeling of general weakness and lassitude is the only obvious, or at least the most prominent, symptom for which the patient seeks relief. We cannot altogether support Dr. Savill in the classification which he has adopted. For the practitioner this chapter may be a useful one but to the student it would prove confusing. Many conditions are mentioned the onset of which may be merely characterised by general debility or, in addition, either by anæmia or emaciation, or both, such as tuberculosis, diseases of the pancreas, chronic visceral disease, functional nervous diseases, nephritis, dyspepsia, and obscure abdominal or pulmonary disease. For a description of these conditions the reader is referred to other parts of the work. We think, however, that for the sake of clearness any reference to them in this chapter should have been omitted. Good accounts are given of chlorosis, pernicious anæmia, syphilis, plumbism, leukæmia, lymphadenoma, hæmophilia, malignant diseases, marasmus in children, senile decay, myxœdema, and Addison's disease, conditions which, although differing in pathology, may rightly all be considered under the classification which is here adopted.

The next chapter has for its title "The Extremities." Dr. Savill's method of approaching his subject from the standpoint of symptomatology is particularly applicable to the various disorders which may attack the extremities (nervous affections excluded). The diagnosis of diseases of the joints is frequently a matter of difficulty but by proceeding according to the directions laid down considerable assistance will be obtained in arriving at a conclusion. The chapter on diseases of the skin is an excellent one and contains a large amount of information clearly and concisely given. The various points for investigation are carefully described and we can recommend a close study of Dr. Savill's remarks to those students who are attending the departments for diseases of the skin at the general or special hospitals.

An account of diseases of the nervous system occupies a large portion of the volume. A few preliminary observations are made on the anatomy and physiology of the central nervous system and we agree with Dr. Savill when he says that Professor Waldeyer's neuron scheme, although not regarded by everyone as the most scientific, nevertheless for clinical purposes is the most lucid and practical yet introduced. The clinical investigation which is required in cases of disease of the nervous system is well discussed and it is shown that if every point be taken in its regular order confusion is not likely to arise. The descriptions of the various diseases are good but we prefer the classification usually adopted in text-books to the one which necessarily follows when symptomatology is taken as the basis. The volume ends with an epitome of clinical bacteriology and the examination of pathological fluids. Numerous illustrations are scattered through the work and some of the diagrams aid greatly in explaining the text.

We have found some faults with Dr. Savill's classification of diseases which is founded on symptoms. On the whole, however, we are of opinion that he has succeeded in producing a very useful manual. We do not think that it will replace the other text-books now commonly used by students but as a companion to them it will be found most valuable. By the practitioner it will be found even of more service, for it will doubtless aid him when he is in attendance on a case of which the diagnosis is obscure and in which the physical signs are not well marked.

Clinical Studies: A Quarterly Journal of Clinical Medicine. By BYROM BRAMWELL, M.D. Edin. Vols I. and II. for the years 1903 and 1904. Illustrated. Edinburgh: R. and R. Clark, Limited. Pp. 384 and 392.

THE two books which form the subject of the present review represent the completed volumes for the years 1903 and 1904 of Dr. Byrom Bramwell's *Quarterly Journal of Clinical Medicine.* Certain of the clinical studies which appear in these volumes have, we believe, been published completely or in part in other periodicals or journals and some of them are already well known to a large number of medical readers. These studies, however, do not belong to the well-known series of Wednesday cliniques, the reports of which form the backbone of the author's quarterly journal. To say the least, however, from the point of view of interest these lectures greatly enhance the value of these two volumes.

Dr. Byrom Bramwell has a delightfully easy style of writing and a direct and forcible manner of appealing both to his audience and to his readers. As a clinical teacher we are disposed to believe that at the present time he has few rivals in this country and certainly no teacher of clinical medicine publishes lectures which make better reading. There is practically no class of medical reader to whom these clinical studies can be otherwise than instructive, whether he be student, practitioner, or teacher. But it is to the practitioner, we believe, that these lectures will chiefly appeal, since they afford him an opportunity of recalling at his leisure memories of that irresponsible assimilation of medical knowledge which distinguished his early educational career as a medical student. For the benefit of those who are unfamiliar with the manner in which Dr. Byrom Bramwell manages his now famous Wednesday cliniques it may be here stated that they are of the nature of demonstrations illustrated by cases, taken down in shorthand and subsequently edited for publication. One of the great features of interest is that the students' answers are reported as well as the teacher's questions. Inasmuch as most of us learn more by our own mistakes and the mistakes of others than by any other means the often incorrect answers of the students impress on our minds the lesson which it is intended to convey. So skilfully are these reports edited that in reading them, in spite of detachment of time and place, we cannot help feeling the atmosphere of the hospital just as we remember it in the days of our youth.

Many of the studies recorded in these volumes, quite apart from their educational value, are weighty contributions to medical literature. For instance, the author's clinical lecture on Aphasia and Will-making has in its medico-legal aspects already become an authoritative document and it very clearly defines the will-making capacities of patients affected with different forms and varieties of aphasia and it describes very lucidly the manner in which wills should be made in the circumstances of defect of speech and the tests to which patients should be submitted in order to ascertain whether they are in a fit mental condition for the testamentary disposal of their properties. Another lecture on Syphilis and Life Assurance which was delivered before the Edinburgh Medico-Chirurgical Society in 1902 must be regarded as among the most valuable contributions to Vol. I. The author gives very strong reasons, which are supported by evidence from his own clinical records, why this disease, contrary to the opinions which are generally held on this subject, must, and does, tend to shorten life and, further, Dr. Byrom Bramwell makes suggestions for estimating the extent to which such lives should be loaded for insurance purposes. In Vol. II. a clinical lecture on Disseminated Sclerosis, with Special Reference to the Frequency of its Incidence and to its Etiology, is well worth reading. It is, indeed, a most important contribution to the literature of this disease and, further, it affords statistical facts with reference to the distribution of the disease respectively among hospital and private patients. Practitioners whose knowledge of some of the rarer and, indeed, of many of the commoner diseases has begun to grow rusty will find the reading of these volumes a very easy and pleasant method of reviving their information on the forgotten points. Among the common complaints which have formed the subject of the author's Wednesday cliniques and are reported in these volumes we may mention Addison's disease, renal calculus, aneurysms, locomotor ataxia, and neurotic vomiting. The studies which deal with these commonplace and every-day diseases are, by the genius of the author, made really interesting and incidentally in discussing these diseases all the newer methods of diagnosis and treatment are referred to, special emphasis being laid on the value of hæmatology and serum-therapeutics in this connexion. Among the rarer diseases which are illustrated in these volumes are examples of pancreatic infantilism, idiopathic infantilism, achondroplasia, and an anomalous or, as the author prefers to call it, a "fruste" case of exophthalmic goitre. Ichthyosis appears to be a favourite subject with Dr. Byrom Bramwell and it is discussed in various studies from several points of view, both singly and combined with other diseases. The author is particularly fond of referring to the influence of constitution and environment on the character manifested by different diseases—that is to say, on the polymorphic character of disease under different conditions—and ichthyosis is a disease which well illustrates this point. Other conditions which are frequently referred to in these volumes are epilepsy, migraine, and chorea, a group of diseases which possess many pathological features in common.

It is impossible to speak adequately of the merits of these two volumes but sufficient has, perhaps, been said to induce practitioners who desire to keep themselves abreast of the modern evolution of medicine to read these volumes at their leisure.

Report on Dourine in Different Breeds of Equines, together with an Account of Vesicular Exanthema and Piroplasmosis which occurred as Complications. By ALFRED LINGARD, M.B., M.S. Durh., D.P.H. Cantab., Imperial Bacteriologist to the Government of India. With 16 illustrations. Calcutta: Office of the Superintendent of Government Printing, India. 1905. Pp. 84, with Appendices pp. xcix.

THIS valuable report deals with dourine as observed in English and Australian thoroughbreds and in Arab stallions which exhibited the disease in chronic, latent, and recent forms. The course of the malady as seen in equines of different breeds in India, together with a short summary of the life history of the trypanosoma, is recorded. Dr. Lingard during his inquiry encountered not only dourine but two other forms of disease—viz., a vesicular exanthema, an infectious sexual disease of horses occurring in an epizootic form, which in its severe form has been mistaken for dourine, and piroplasmosis, in which an organism was found in the red corpuscles akin to, but not identical with, that producing hæmoglobinuria in Texas fever.

Dr. Lingard first gives a *précis* of the cases of spontaneous or naturally contracted dourine in stallions observed at the Babugarh Depôt and at Bareilly, and of experimental cases of dourine in equines, dogs, rabbits, and guinea-pigs. He next proceeds to the facts bearing on the etiology of the disease. As regards the period of incubation, this was found a most difficult matter to obtain accurately in spontaneous cases of the disease, but experimental cases showed that if dourine is suspected in any given equines the veterinary surgeon ought to be on the alert any time between the tenth and fiftieth day after the date of the primary covering. There are certain symptoms appearing in the early stage between covering or inoculation and the eruption of the first cutaneous plaque which can help the observer in his diagnosis, such as congestion of the vaginal mucous membrane and the formation of vesicles, more or less persistent tumefaction of the labia, and swelling and œdema of the vaginal mucous membrane. The simultaneous occurrence of all of the above symptoms should lead the observer to suspect a case of dourine. The period between the covering or inoculation and the appearance of the first plaque is variable both in stallions and mares, especially in the former. Until the plaques appear, in the large majority of cases it has been found that the disease has not become generalised but the *materies morbi* is lying dormant in some region of the body. Thus in some cases the disease has remained latent for more than 12 months. In other cases only 34 days elapsed between the date of covering and the eruption of plaques. In general, however, it is concluded from the experiments that the length of time between the covering or inoculation and the appearance of the primary plaque varied between 24 and 34 days. The plaques again were found to appear during a period varying from

17 to 313 days. Their commonest sites were the neck, chest, abdomen, croup, and shoulders, whilst in some cases they were more or less localised in some particular region. The various forms that the plaques assume are well described; there were in 443 plaques in equines 313 circular and 130 oval or irregular. In size, where few they are fairly large, and where numerous they are smaller. They may vary when circular from 0·5 to 5 inches in diameter, and when oval or irregular from 0·75 by 0·5 to 8 by 5 inches. Respecting the length of the individual paroxysms and intermissions, the shortest period of a paroxysm was 24 hours and under, while the longest was four days. The shortest period of an intermission was one day and the longest was 138 days. As a rule the plaques only appear once but in a certain percentage of cases they reappear on the same spot. Weakness in the loins and paraplegia were found to attack stallions less frequently and at a later date than mares. Not infrequently a stallion may exhibit for a long time a symptom pointing to dourine—viz., swelling of the sheath—but an absolute diagnosis cannot be arrived at till further symptoms have developed. In these cases Dr. Lingard recommends bleeding, as loss of blood will bring out the eruption of plaques and thus much time and expense will be saved.

With regard to the diagnosis between surra and dourine, the chief points of distinction are that in surra the paroxysms are usually accentuated by the manifestation of well-marked conjunctival petechiæ, high fever, and the presence of large numbers of hæmatozoa. The disease is an acute one, being fatal within two or three months; the spleen is always enlarged and the vulva and vagina are rarely implicated. In dourine, on the contrary, there is a complete absence of conjunctival petechiæ, the temperature rarely exceeds normal limits, and the protozoon may be only present in small numbers and undiscoverable. The disease is essentially chronic, death being rare before six months. There may be no perceptible enlargement of the spleen and the vulva and vagina are affected.

With regard to the period of the disease during which the trypanosoma could be discovered in the vaginal mucus of the affected animal, it was found that it could be observed as early as the seventeenth or eighteenth day after the covering. Lastly, as regards the exciting causes bringing about a primary or further eruption of plaques, it was found that certain depressing conditions due to fatigue, from whatever cause, would act thus.

The next section of the report deals fully with the symptoms. These are referable to (1) the genital organs, (2) the skin, and (3) the nervous system. They in the first phase are seen to differ in the stallion and in the mare. The skin manifestations are those of plaques, disseminated urticaria, and an eruption of small vesicles. In the last phase of the disease the animal suffers from progressive emaciation, weakness, and anæmia. Paraplegia finally sets in and then death ensues from exhaustion or pulmonary complications. Towards the end hæmaturia or hæmoglobinuria may supervene. Next follows a section on the diagnosis of the affection considered in its clinical and in its microscopical aspects. Clinically, the appearance of the plaque is the most important fact. An excellent table of the comparative symptoms of surra and dourine is given.

With regard to the duration of the disease in India Dr. Lingard has found it still in an active state after an interval of three years from the exhibition of the first symptom. The mortality has been 30·77 per cent. It is greater in mares than in stallions and the disease runs a more rapid course in imported than in country-breds. As regards treatment no satisfactory measure has as yet been found. Dr. Lingard has proved experimentally that the trypanosomata of dourine and surra may be cultivated *in vitro* but sufficient time has not yet elapsed to allow of experimental inoculation being made with cultivations far removed from the initial virus. In this method would seem to lie the only chance of curing the disease. For controlling the disease in the matter of prophylaxis, the affected animal must be protected from flies which carry the contagion and the stable floors must be kept clean and disinfected.

Space will not permit us to enter into the remaining features of this lucid report; the reader will find some excellent observations on the trypanosoma of dourine, on the post-mortem appearances, on the vesicular exanthema of horses, and on piroplasmosis. The book is illustrated by some excellent plates. The whole work represents an immense amount of labour and is worthy of the author. He is sincerely to be congratulated on the result of his labours.

A Revision of the Anophelinæ. By Lieutenant-Colonel G. M. J. GILES, F.R.C.S. Eng., &c. London: Bale, Sons, and Danielsson. 1904. Pp. 47, with 1 plate and 13 figures in the text. Price 2*s.* 6*d.* net.

AS its sub-title informs us, this pamphlet is a supplement to the author's "Handbook of the Gnats or Mosquitoes" and it essays to bring up to date our knowledge of the sub-family anophelinæ. Lieutenant-Colonel Giles is working in friendly rivalry with Mr. Theobald, to whom has been intrusted the duty of studying the British Museum collections of these dipterous plagues and who is continually bringing out memoirs and additional records concerning the immense variety of species of culicidæ. The great rapidity with which this line of investigation is being pursued at the present time will, we fear, be the cause of a good deal of confusion in the future as to the limits of species and genera. A cool and even armchair revision of the accumulated facts will be the duty of some specialist by-and-by. In the meantime it is plain that these "matériaux pour servir à l'histoire" will form the groundwork of future knowledge of the family culicidæ. Lieutenant-Colonel Giles himself is a little sceptical as to the real existence of the 96 species of anophelinæ which he duly records and observes in his prefatory remarks that when the study of the larvæ has advanced to a higher pitch a large number of reputed species will have to be dropped as mere synonyms. To the systematist only secondarily interested in the germ-carrying powers of mosquitoes the infinite multitude of species and their diverse geographical distribution are at present somewhat of a puzzle. All this requires careful sifting out and cases of occurrence of apparently the same species in the most widely separated localities must be checked by criteria which will probably ultimately be arrived at. At present the general opinion will be that there is not much relation between classification and distribution. In this pamphlet Lieutenant-Colonel Giles deals only with matters of classificatory interest and the value of his diagnoses of genera is largely increased by the clear figures of generic characters with which he begins the brochure.

LIBRARY TABLE.

An Introduction to Midwifery: A Handbook for Medical Students and Midwives. By ARCHIBALD DONALD, M.D. Edin., Gynæcological Surgeon to the Manchester Royal Infirmary. With numerous Illustrations. Sixth edition. London: Charles Griffin and Co. 1905. Pp. 192. Price 5*s.* net.—This, the sixth, edition of this little work has been carefully revised in the light of the Midwives Act and much trouble has been taken to make clear the conditions in which the midwife may take responsibility and those in which she must call in a medical man. Some extracts from the rules framed by the Central Midwives Board for the regulation, supervision, and restriction within due limits of the practice of midwives are given in an appendix. The author has endeavoured to treat the subject in a manner that will be found not too elementary, in a guide to attendance on labour, for the student and at the same time not too advanced for the more intelligent class of midwives. The first chapter is intended for the midwife alone. The book is well written and well illustrated and fully deserves the measure of popularity which the former editions have enjoyed and which, we think, will be continued to the present one.

The Oxford Shorthand. Dover: The Oxford Shorthand. 19th edition. Pp. 36. Price 6*d.*—It is stated that this shorthand was being constructed about the time of the First Great International Shorthand Congress held in London in 1887; that the amount expended upon it now approaches £4000; and that it was awarded the Exhibition Grand Gold Medal in 1889 A number of favourable opinions of the public and the press respecting it are quoted. The system is based on the relative frequency of certain words. Passages, containing in all 50,000 words, were taken from ten standard authors—5000 words from each. At the top of the poll was the word "the" which came 3959 times. Similarly, "of" occurred 2739 times and "and" occurred 2049 times. It was finally found that a list of 280 words accounted for nearly four-fifths of the 50,000 words. The list of outlines of words to be learnt was therefore arranged in descending order of frequency of occurrence, the first word being the most important because the most frequent, the second the next most important, and so on all the way down. It is claimed that the shorthand can be written very rapidly. A note at the bottom of an accompanying circular says, "Books only, 5*s.* net, post paid."

Poisonous Plants of all Countries. By A. BERNHARD SMITH. Bristol: John Wright and Co. 1904. Pp. 88. Price 2*s.* 6*d.* net.—This will be found a useful little book of reference dealing not only with plants undoubtedly poisonous but including many plants the toxic effects of which are not very great. After a table of the poisonous principles contained in the plants described, the author gives a short glossary of botanical terms, followed by a description of the poisonous plants classified under the names of the various parts of the body upon which the poisonous principles act, the symptoms produced, and the suggested treatment. An appendix contains a list of reputed poisonous plants. There are two coloured plates of European fungi and a good index.

Merck's Annual Report for 1904. London: 16, Jewin-street, E.C. 1905. Pp. 241.—Merck's Annual Reports fill an important place in pharmacological literature. This recent number represents the eighteenth volume of the series. It is fair to state that the publication consists in reality of an authoritative epitome of recent therapeutic literature and that its references are by no means restricted to the particular pharmacological products of the Darmstadt factories. The present volume gives a brief review of the physiological action and therapeutic results obtained as recorded in the medical literature of 1904. Chapter and verse are given in each case. The book is sent free to medical men on application.

Appendix to Squire's Pocket Companion to the British Pharmacopœia. London: Squire and Sons. 1905. Pp. 35 - xxv.—This useful publication enables the practitioner at a glance to acquaint himself with the recent contributions that have been published in regard to drugs and new therapeutic agents. It is, in fact, a supplement to the excellent Pocket Companion published by Messrs. Squire, thus serving to bring that volume up to date. In short, it is a digest of recent pharmacology and as such will be appreciated by the medical practitioner desirous of keeping pace with therapeutic and pharmacological advance.

A Synopsis of the Principal Changes in the United States Pharmacopœia effected by the Eighth Decennial Revision. By W. HARRISON MARTINDALE, Ph.D. London: H. K. Lewis. 1905. Pp. 36. Price 2*s.*—The publication of this synopsis of the recent revision of the United States Pharmacopœia is of interest inasmuch as it brings conveniently to the notice of the medical practitioner and of the pharmacist the chief alterations which have been made. Americans are certainly not behind in therapeutic and pharmaceutical matters and we must often own in this country to taking a leaf out of the American book. The revisions here recorded in a convenient form by Dr. Martindale are instructive and the hints thereby given will doubtless be noted by our Pharmacopœial authorities.

JOURNALS AND MAGAZINES.

Medical Chronicle.—The July number opens with an interesting article by Dr. J. Dreschfeld upon Syphilitic Affections of the Central Nervous System, treatment by mercurial inunction being advised together with iodide of potassium internally. Contra-indications to the use of mercury are a low state of health, great emaciation, and the existence of optic atrophy. Dr. W. E. Fothergill, discussing Variations of the Menstrual Functions in Anæmia, gives an account of recent views as to the nature of this function which is regarded as a means of ridding the female system of nutritive material laid up in excess of the requirements of the organism. When pregnancy occurs these are used for the nutrition of the fœtus. Amenorrhœa may be produced either by a failure of the anabolic process just alluded to or by lack of a stimulating secretion formed by the corpus luteum of the ovary.

Looking Back.

FROM

THE LANCET, *SATURDAY*, August 18, 1827.

EVERY man, according to the lawyers, who conducts his own cause, has a fool for his client; and it is certain, that of all persons medical men are the least liberal in conferring the benefits of their professional experience upon themselves. The lawyer grumbles over his losses, without calling the "glorious uncertainty" to aid his cause, holding it, as he does, of course, specially in trust for the benefit of the people alone; and the physician who prescribes for the ailments of a thousand, appears to be regardless of his own, which are, perhaps, fast hurrying him to the bourne of his fathers. Strange as it may appear, that the man who has bought a ticket in the lottery of physic, with all the chances which a knowledge of anatomy and the various collateral sciences may be supposed to give him, should decline drawing, when himself, the preservation of his own existence, is the prize—still more strange is the state of society, when it is pretended and industriously inculcated and believed, that any man wanting these requisites can, by means of medical guides, administer successfully to the sad catalogue of diseases which infest the human frame! The people are deceived. Buchan and the writers on domestic medicine have done more for physicians, than the readers of these sacred tomes are perhaps aware of. Narcissus like, the patient pines over his own image, and gathers fresh tortures at every page of his reading.[1]

PHILOMATIC SOCIETY OF PARIS.

A Female with Three Breasts.

M. Adrien de Jussien related the case of a woman having three breasts, one *situated in the groin*, with which she occasionally suckled. This was the more remarkable, as her mother had three breasts, but all situated on the chest.

---

[1] Excerpt from review of "*Modern Domestic Medicine, or a Popular Treatise, illustrating the Character, Symptoms, Causes, Distinction, and correct Treatment, of all Diseases incident to the Human Frame; embracing all the modern improvements in Medicine, with the opinions of the most distinguished Physicians,* &c. [The title would fill a page] By JOHN THOMAS GRAHAM, M.D., Member of the Royal College of Surgeons, &c. 8vo. pp. 564. London, 1827. Published by Simpkin and Marshall."

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

(1) "TABLOID" HEMISINE; (2) "SOLOID" HEMISINE COMPOUND WITH EUCAINE; AND (3) "SOLOID" HEMISINE WITH ATROPINE SULPHATE.

(BURROUGHS, WELLCOME, AND CO., SNOW HILL BUILDINGS, LONDON, E.C.)

1. THE tabloid hemisine, the name given by Messrs. Burroughs, Wellcome and Co. to the hæmostatic principle of the suprarenal gland, contains 0·001 gramme of the derivative. This tabloid is convenient for administration by the mouth to arrest gastric hæmorrhage or for the sake of its tonic effect on the heart and vessels. 2. The soloid hemisine compound contains 0·0001 gramme hemisine, 0·08 gramme sodium chloride, and 0·02 gramme eucaine hydrochloride. This is useful for the preparation of a solution for intravenous or intramuscular injection. 3. The soloid hemisine with atropine sulphate contains 0·0002 gramme of hemisine with 0·001 gramme of atropine sulphate and is used as an intravenous injection in cardiac failure or collapse or as an intramuscular injection in post-partum hæmorrhage.

METAKALIN.

(THE BAYER CO., LIMITED, 19, ST. DUNSTAN'S-HILL, LONDON, E.C.)

The antiseptic constituent of metakalin is meta-cresol combined with an alkali. The antiseptic and disinfectant power of meta-cresol is well known and supersedes that of the other cresols. Metakalin is supplied in the form of tablets of 15 grains each and one tablet dissolved in four ounces of water gives a 1 per cent. solution which is convenient for ordinary purposes. The solution also has the advantage of being a distinct detergent.

ITONA BREAD.

(E. G. MOORE, 164, REGENT'S-PARK-ROAD, LONDON, N.W.)

This bread is distinguished analytically by containing a maximum proportion of the nutritive constituents of wheat, while the coarse branny envelope, which is a source of irritation in the alimentary tract, has been carefully eliminated. Moreover, the bread contains an excellent proportion of mineral salts, including the essential natural phosphates. Our analysis showed as much as 7·05 per cent. of proteid in the moist bread, the moisture amounting to 41·50 per cent. The loaf is of a light-brown colour, well baked, and of uniform texture; the flavour is very good and superior to that of bread made from an inferior quality of flour. We have more than once urged the importance of keeping up a high standard of quality of bread such as is represented in this specimen.

WOODHOUSE BLEND WHISKY.

(R. B. SMITH AND SON, PERTH, N.B.)

The analysis of this whisky gave the following results: alcohol, by weight 42·29 per cent., by volume 49·81 per cent., equal to proof spirit 87·29 per cent.; and extractives, 0·03 per cent. As regards secondary products the following were the results given in grammes per 100 litres of absolute alcohol present: volatile acidity, calculated as acetic acid 103·00; aldehydes, 20; furfural, 2·22; ethers reckoned as ethyl acetate, 56·32; and higher alcohols, 132·40; total, 318·94. These figures indicate a blend as described, the furfural, ethers, and higher alcohols being somewhat under the amount generally found in an all-malt whisky. The spirit gives distinct evidence of age and is smooth to the palate. There was no indication at all of the presence of acrid products. The flavour is delicate. This spirit compares very favourably with specimens of its class.

SPARKLING BILZ.

(THE HARTMAN BILZ BEVERAGE COMPANY, 11, QUEEN VICTORIA-STREET, LONDON, E.C.)

For all practical purposes this is a non-alcoholic beverage containing less than 2 per cent. of proof spirit which is regarded as the limit for revenue purposes. It is pleasantly sparkling, has a bright amber colour, and possesses a peculiar flavour suggestive of fruit essences. There are two qualities, one described as "dry sparkling" and the other as "sweet sparkling," but as regards sugar there is not much difference according to our analysis in the amounts between them. Thus, in the sample described as dry the sugar amounted to 10 per cent. and in the sample described as sweet to a little over 11 per cent. In our opinion both are too sweet for the purpose of a beverage, but of course palates differ. We do not regard it as an ideal non-alcoholic drink.

SILKY FIBRE ASEPTIC HANDKERCHIEF.

(THE TOILET NOVELTIES CO., 5, UNITY-STREET, COLLEGE GREEN, BRISTOL.)

We have previously noticed this excellent material but it has since been improved and handkerchiefs made of it may now be obtained in what is called the new No. 12 pocket-book containing 18 full size handkerchiefs. The result is a neat case which is not bulky and is quite convenient for carrying in the pocket. The material has a silky lustre and touch and its texture is rigid enough for the purpose in view. The handkerchiefs are treated in the course of manufacture with an odourless antiseptic and they contain nothing but the silky fibre. When soiled—and they are very absorbent—they may be burnt or even disposed of down the sink as they readily disintegrate in water and therefore are not calculated to choke the pipe. Their use, of course, in influenza, common colds, and tuberculosis of the respiratory organs, and their subsequent destruction by fire is an eminently hygienic measure.

(1) PLASMON BLANCMANGE AND (2) PLASMON CUSTARD POWDER.

(INTERNATIONAL PLASMON, LIMITED, FARRINGDON-STREET, LONDON, E.C.)

Many custard powders and blancmange powders when prepared result at their best merely in a starch jelly which in no way represents the nourishing properties of a genuine custard. A proper custard at any rate should be made from eggs and milk and then it is an article of decided nutritive value and appetising quality containing a good proportion of proteid. In plasmon custard the proteid is represented by milk proteid, so that probably the resulting preparation is of decided nourishing value. Plasmon custard powder, according to our analysis, contains over a fourth of its weight of proteid and plasmon blancmange over a fifth of its weight of proteid. The preparations therefore are a distinct dietetic advance on the custard or blancmange which contains little else than starch.

KASTILIS.

(CHARLES BILLING, 43, HANLY-TERRACE, ENFIELD LOCK.)

Theoretically, ordinary borax is an acid borate of soda, just as bicarbonate of soda is an acid carbonate of soda, but, as is well known, borax is decidedly alkaline to litmus test papers, boric acid in fact having a very feeble acid power. Nevertheless, there is reason for believing that in spite of this feeble acid power borax is not altogether compatible with soap, for when borax is mixed with soap some fatty acids, it is stated, separate. This has suggested the preparation of monoborate, which means saturating the excess of boric acid in borax with soda or potash or both. The resulting solution of monoborate is called "kastilis" which may be incorporated with soap without setting free any fatty acids. The idea seems to us to be sound and certainly an excellent cleansing soap is produced. It has a pleasant, soft feeling when lathered in the usual way and leaves the skin smooth and clean. It is stated further to be soothing in irritable conditions of the skin.

CRÊME DE MENTHE.

(Get Frères, Révèl, France; Agency, B. Lauriez, Paris, and 6, Fenchurch-buildings, London, E.C.)

For all intents and purposes this is a liqueur. It is a delicately green coloured and somewhat syrupy fluid with an agreeable flavour of oil of peppermint. Analysis gave the following results: alcohol, by weight 23·62 per cent., by volume 28·77 per cent., equal to proof spirit 50·41 per cent.; solid constituents, 48·83 per cent.; and mineral matter, 0·02 per cent. We think the quantity of sugar might be reduced with advantage as practically all the solid constituents consist of sugar, that is nearly 50 per cent. The sugar readily crystallised on exposure of the liqueur to dry air. The liqueur is a pleasant carminative and stimulant by virtue of the spirit and the oil of peppermint contained in it. Oil of peppermint, moreover, has decided antiseptic power, so that it serves as an anti-fermentative in dyspepsia.

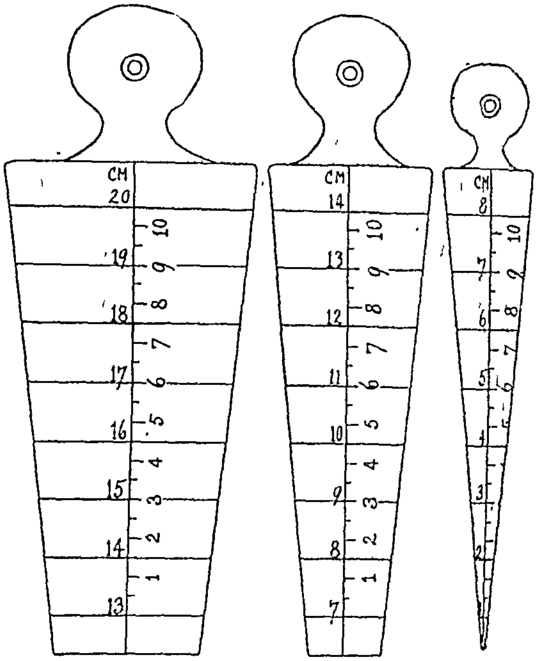
THERAPEUTIC YEAST.

With reference to a notice which appeared under the above heading in The Lancet of June 17th, 1905, Professor E. Jacquemin of Malzèville, near Nancy, who introduced the pure grape ferment there described (Messrs. Cooper and Co. of 80, Gloucester-road, London, S.W., acting as agents), issues in a communication which has reached us a warning note to the medical profession as to imitations which he states are being offered. He emphasises the importance of employing for therapeutic purposes the pure ferment of the grape only and states that neither the Pasteur Institute nor the late M. Pasteur has been, or is, in any way associated with these products, as might be implied from the way in which the name of the late distinguished *savant* is being connected with them.

New Inventions.

CONES FOR MEASURING THE CIRCUMFERENCE OF ORIFICES.

In the course of post-mortem examinations occasions arise when one has to measure accurately the size of orifices in the heart and elsewhere. In the Royal Infirmary of Edinburgh cones indicating the diameters in inches have been used for many years for this purpose. These are admittedly unsatisfactory, as in calculating the circumferential measurements from the diameters any error which has crept in, for example, through stretching of the orifice, is multiplied 3 1/7 times. Other means have been adopted—e.g., metal balls of different sizes, and I believe that on the continent cones similar to those I figure have been employed, but I have been unable to obtain either specimens or descriptions of them. Professor W. S. Greenfield of Edinburgh has a cone of this kind which was made for him 25 or 30 years ago, but owing to its wide angle and close markings it is somewhat difficult to use. To supply this want and to obviate these objections I have designed the cones figured in the sketch which is drawn to a scale of one-half the actual size. The sides of the cones are inclined to each other at an angle of 12°, this facilitating their introduction and making for accuracy in the measurements taken. The transverse lines drawn round the cones indicate circumferential measurements in centimetres. These lines are one and a half centimetres apart. To show this a line divided into centimetres is drawn from base to apex of each cone crossing the transverse lines. A longitudinal scale is thus furnished which is useful in localising exactly the site of constriction, for example, in funnel-shaped openings. On the other side of the longitudinal line marks were introduced in the case of the first cones made, dividing the distance between the transverse lines into fifths, thus enabling circumferential measurements to be recorded in fractions of centimetres if required. These have been omitted in the sketch. I have tested the various measurements and find them to be very accurate. The cones are solid, being made of boxwood.



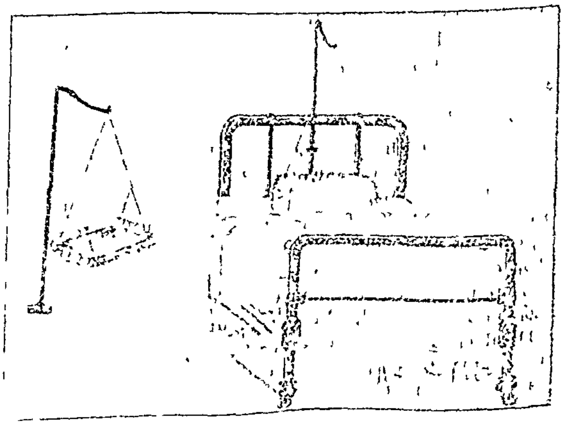
Cones for measuring circumference of openings.

I have to thank Messrs. Archibald Young and Son, Forrest-road, Edinburgh, for the care and patience with which they have carried out my designs and also for furnishing the block illustrating this note.

Theodore Shennan, M.D., F.R.C.S. Edin.,
Pathologist at the Royal Infirmary, Edinburgh.

THE GRAHAM HEAD AND SHOULDER SUPPORT.

We have received from Mrs. Frances Furnivall, of 13, Fawe Park-road, Putney, an illustration and short description of a head and shoulder rest which, she states, can be adjusted to any form of bedstead in a few minutes and affords rest and ease to the bedridden and to those confined to bed for a period through suffering. It consists of a metal rod having very much the appearance of the figure 7 which is clamped to one of the perpendicular rods at the head of the bedstead. From the projecting portion or head of the 7 depend two inverted Y slings holding a support for a pillow. This device no doubt allows of easy movement of the head but we have not tried the apparatus itself. The price of the head and shoulder rest is £1 1s.



THE BRITISH MEDICAL ASSOCIATION.

MEETING AT LEICESTER.

THE SECTIONS.

LARYNGOLOGY, OTOLOGY, AND RHINOLOGY.

WEDNESDAY, JULY 26TH.

The discussion on the papers of Dr. W. MILLIGAN, Mr. E. B. WAGGETT, and Mr. T. G. OUSTON on

The Lines of Treatment in preventing Acute Middle-ear Suppuration from becoming Chronic

was continued by

Mr. R. LAKE (London) who said that the efficiency of a perforation for drainage depended upon its size and site. He was in favour of free incision of the drum before marked bulging occurred. He would not operate upon the adenoids when the ear disease was acute.

Dr G. W. HILL (London) agreed with Mr. Waggett that the acute cases got well when treated. He (Dr Hill) incised the membrane when bulging and afterwards performed politzerisation.

Mr. L. A. LAWRENCE (London) considered that amongst hospital out-patients a large number of acute cases became chronic through the treatment not being carefully carried out by the patients.

Dr. W. JOBSON HORNE (London) was inclined to the view that a large number of cases of middle ear suppuration were chronic *ab initio*. He based this opinion upon the results of a bacterioscopic investigation conducted post mortem on subjects free from ear disease. In the middle ear were found organisms of a non pathogenic nature; under certain conditions these might assume a pathogenic rôle. As regards treatment a free incision of the drum of an exploratory nature might often be avoided by previously withdrawing the contents of the middle ear under all aseptic precautions with a fine and suitable pipette. The results of the puncture would decide the operator as to the necessity of a free incision, and a bacterioscopic examination of the fluid drawn off would throw light not only on the exact etiology of the case but also on the prognosis of the acute condition becoming chronic.

Dr J. KERR LOVE (Glasgow) knew of no reasons against politzerisation but he did not practise it after paracentesis of the drum He preferred the dry treatment of acute cases

Dr. J DUNDAS GRANT (London) advocated aseptic precautions in performing paracentesis In acute middle-ear suppuration in children he thought of naso pharyngeal treatment, and in adults of tympanic treatment.

Dr. HERBERT TILLEY (London) had found that the use of leeches in acute cases led to confusion by the œdema which they induced; it was difficult to decide how much of the œdema was due to the leeches and how much to the mastoid conditions.

Dr. J. MIDDLEMASS HUNT (Liverpool) recommended the widening of the perforation in cases that did not improve

The PRESIDENT of the section, Dr. F. W. BENNETT (Leicester), in summing up the discussion, considered that knowledge of the subject had suffered through insufficient progress with bacteriological investigations. The dangers from the use of inflation he thought had been overstated; at the same time he considered that sufficient attention was not paid to keeping the bags used for the purpose in a clean and aseptic condition.

Dr. MILLIGAN, in replying, thanked the members for the attention which they had given and said that he had expected hostile criticism of some of the operative measures which he had submitted.

Mr WAGGETT, in replying, said that in the routine treatment by general practitioners paracentesis and politzerisation were not called for in every case of earache On the other hand, paracentesis must not be delayed until "to morrow morning" if certain conditions called for it; one of these conditions was the presence of true opaque pus in the tympanum. Many speakers had said that politzerisation did no harm. Could it do any real good? He believed that it could, and did, do actual harm occasionally. Experience had given him complete confidence in removing adenoids during an acute muco-purulent catarrh of the middle ear Many tender mastoids accompanied with fever got perfectly well; but even in the absence of the classical signs of mastoiditis, *including dropping of the postero-superior* wall of the meatus, a very copious purulent discharge compelled the surgeon to operate or else to risk the patient becoming affected with chronic otorrhœa.

Dr. ALBERT A. GRAY (Glasgow) read a paper on

The Pathological Conditions found in a Subject who had suffered from Deafness during Life.

He said that the individual from whom the temporal bones were removed had suffered from almost absolute deafness and very severe tinnitus for a period of 17 years before her death at the age of 71 years. The patient died from malignant disease of the uterus and in addition to the conditions relative to the cancerous affection the following were noted in regard to the anatomical changes found *in the temporal bone* and the adjacent structures. The bones of the skull were remarkably soft and the saw went through the calvarium almost as if the bone were of the consistency of hard cheese The greater part of the temporal bone was also soft in character and the dense ivory-like capsule of the labyrinth was much reduced in thickness The mucous membrane of the tympanum and Eustachian tube was normal throughout. The malleo-incudal joint was ankylosed *on the right* side but not on the left On both sides the stapes was completely ankylosed in the oval window, the ankylosis being bony throughout. In the left membranous labyrinth the changes in the bony capsule were found to have produced distortions in the two limbs of the posterior canal by encroaching on its lumen The cochlear branch of the auditory nerve was atrophied at least in the two upper turns of the cochlea. The ligamentum spirale appeared to be of a less dense nature than normal, though this may have been due to old age and not to the disease In the *right membranous* labyrinth there was found to be no actual distortion. The ligamentum *spirale* was atrophied as was also the cochlear branch of the nerve There were two masses of calcareous deposits, one in the common limb of the posterior and superior canals and the other in the posterior limb of the horizontal canal.

Dr W S SYME (Glasgow) demonstrated

A Pair of Forceps for Operations on the Maxillary Antrum.

The instrument had been designed by Dr. Syme for the purpose of removing the inner or nasal wall of the antrum of Highmore to permit of sufficient drainage. The forceps were constructed with suitable curves for introduction with the blades closed through the right and left nostrils respectively. They *differed* from those in use inasmuch as they could be employed for the purpose indicated through the nostril and not through the opening made externally, and were more adaptable for the removal of the inner bony wall down to the floor of the nose.

NAVY, ARMY, AND AMBULANCE.

WEDNESDAY, JULY 26TH.

Surgeon-Lieutenant Colonel H W. KIALLMARK (London) was the President of this section and called upon Fleet Surgeon C M BEADNELL, R N., to communicate a paper

On the Disposal of our Wounded in a Naval War.

He stated that some of the suggested methods of dealing with the sick or injured on board a man-of-war in action were: 1 To throw them overboard. 2 To allow them to lie *in situ*, with first-aid dressings or appliances put on by themselves, their comrades, or the medical staff, until a lull in hostilities permits (*a*) the medical officer of the ship to repair on board or on deck, as the case may be, and to administer first aid to the wounded *in situ*, or, if there be no medical officer on board, (*b*) the evacuation of the wounded into another man of-war, a hospital ship, or shore hospital; and (*c*) an organised transport of the wounded into certain non-protected regions of the ship 3. *To have* an organised system of transport *via* vertical passages to locations specially constructed. 4. To convey the wounded into armoured locations situated in the upper works above the water-line. It was suggested that in a modern action every combatant should wear a life-belt and when incapacitated should be dropped overboard, but to throw an unconscious man into the water was to commit murder, to say nothing of the danger of shock and of sharks First aid to the injured was taught to practically every officer and man in His Majesty's navy. The dressings applied, the man should be carried below. All small craft would be compelled to evacuate their wounded at the first opportunity. In their larger ships it had been advised that the wounded should be left lying where they fell, then when a remission in hostilities occurred the surgeons should be summoned from below to administer first aid. Any unprotected part of a ship was utterly impracticable for administering surgical relief to the wounded. To allow a medical officer on deck during fighting was quite inadmissible. He might chafe and fret at being kept below, but below he must be until all shell fire was over. It was not unreasonable to ask for a specially prepared locality in which the surgeon might attend to urgent cases. Ships must have an easily accessible hospital of combat in which it would be possible to perform surgical operations. There was a tacit admission on the part of most naval officers that the wounded must be got down below in some way or another, so why not have a prearranged location laid down in the primary plans of the ship. Given uniform types of vessels and the inclusion of a hospital of combat in the original plans there would be little disagreement amongst medical men concerning the matter. The hospital of combat should, if possible, be double (one forward, and one aft) in the larger vessels, to allow of subdivision of the wounded into urgent and less grave cases. In vessels of a medium size a single hospital of combat must suffice. There must be free and easy means of ingress and egress by vertical passages. Each hospital of combat should be in direct communication with the fighting decks by means of passages distinct from ammunition hoists and protected, if possible, by armour. On the verge of hostilities it is advisable to shift the men into clean clothing so that any shreds carried into their bodies by shell fragments would, at any rate, be comparatively clean. During the fighting those wounded able to walk would proceed to the nearest dressing station; those more seriously hurt should have first aid dressings applied to them on the spot and at the first opportunity should be detruded to the hospital of combat. Throughout an action all watertight doors were closed and were only opened during some of the interregna of battle. Under present conditions the only uninterrupted viaducts between the fighting and protected decks were the ammunition hoists and to use them for the wounded would interfere with one of the most vital conditions of modern warfare, to wit, the rapid and uninterrupted feeding of the guns. "Ye cannot serve God and mammon," and an ammunition hoist could not perform adequately the function of raising projectiles and detruding wounded. What was wanted was the coöperation of a medical officer with those superintending the construction of the vessels in order to advise upon questions pertaining to the sick bay and the hospital of combat. Another objection urged was that such a hospital of combat would be insufferably hot but much might be done in the way of avoiding excess of heat by insulating the hospital of combat by a layer of cement. Hospital ships were the *sine quâ non* of a modern naval war with its prolonged action, many minor engagements, and vast area of belligerency. To each naval station there should be at least one hospital ship which should be expressly built on the lines of a modern hospital and should be capable of accommodating about 400 to 500 men. It was the urgent duty of the naval constructors to provide well-ventilated, well-lighted, and well-protected hospitals of combat in communication with the upper deck by means of straight passages, allowing of an untrammelled to-and-fro excursion of the apparatus of transport and the rapid evacuation of the wounded from the fighting decks above.

Fleet Surgeon O. W. ANDREWS, R.N., communicated a paper entitled

Arrangements for the Treatment of Wounded in Action on Board H.M.S. "Magnificent" ("Majestic" Class).

He stated that ambulance instruction was given systematically by the surgeon and when reported fit the class was examined by the fleet surgeon. When an action was expected all surgical instruments, dressings, and drugs not required for first aid would be removed to that part of the middle deck generally known as the bag flat. Two dressing stations had been selected, one on the starboard side of the main deck abaft the fore turret and the other on the port side of the main deck before the after turret. As regarded the question of protection, it had been found by practical experience in the present war in the Far East that there was no place in the ship which could be considered safe in action, so that when it was suggested, as had frequently been done, to remove the medical officers "to some place of safety until after the action is over" the suggestion was based on an assumption which was purely hypothetical, as it was not possible for anyone to say which was the safest part of the ship. The conning towers were generally assumed to be the safest places in a ship and for that reason were, as their name implied, set apart for those conning the ship or fleet, but no one could reasonably expect the medical officers to be placed here in action, in places barely large enough for the purpose for which they were designed, yet if the medical officers were to be kept as much as possible from risk of injury until after the action was over that was logically their only position if that idea was to be carried out. Although those two principal dressing stations had been arranged with the idea that one medical officer and half of the staff enumerated would be at those places yet it was not desirable or expedient that the medical officers should be confined to those posts. The medical officers should regard those posts rather in the light of rendezvous where they might be found and they should be free to go wherever their services were most urgently required. Every endeavour should be made to render first aid to the wounded where they fell and it was with that idea that so many men were nowadays instructed in ambulance work. Men seriously wounded were liable to have their injuries aggravated and shock and hæmorrhage increased by being moved during an action. Yet fighting being the object and only object of a man-of-war the wounded could not be allowed to interfere with the fighting efficiency on which not only the safety of the ship or fleet but also of the nation depended, so that not infrequently it might happen that men seriously wounded would have to be placed outside a casemate or turret and removed by the bearer party to the arranged stations after having first received an injection of morphine in order that their suffering and pain might be reduced to a minimum. For this last purpose it was recommended that a plentiful supply of hypodermic syringes should be issued in war time for distribution at the discretion of the medical officer to persons instructed in the method of injecting morphine solution and as to the dose which was to be injected. Before going into action the men should wear clean underclothes and clean clothes generally. When an action was over the wounded requiring major operations would be removed to the place arranged for operations or to a hospital ship. The place selected for operations would depend entirely on the damage which had been done to the ship.

Fleet Surgeon THOMAS AUSTEN, R.N., contributed a paper on

The Collection and Distribution of Wounded in a Modern Cruiser Engagement.

He observed that on Feb. 9th last year he had the opportunity of assisting in the treatment of the wounded on board the Russian second-class cruiser *Varyag*, of 6500 tons, 23 knots speed, 12 six-inch guns, and 535 men, as the result of her 40 minutes' engagement with a Japanese squadron. She had been principally opposed by the *Asama*, a first-class cruiser of 9750 tons, 22 knots, 4 eight-inch guns, 14 six-inch guns, and 750 men. The *Varyag* had been forced to withdraw in a badly damaged state and the result might be taken as a fair type of the likely conditions ensuing on a bold cruiser engagement. The *Varyag* was an unarmoured cruiser and the *Asama* was an armoured cruiser. Half an hour after the engagement was over the *Varyag* returned to Chemulpo harbour, listing to port and her after end burning. She had been struck below the water line and her upper decks and fighting tops had been swept by shell fire. None of the men employed below had been injured but of the 150 engaged about the exposed parts 40 had been killed outright and 68 wounded. Shimose—the explosive used in the Japanese service—was as high in explosive force as, if not higher than, any of the modern powders and the shell breaks up into a large number of small fragments eminently suitable against unarmoured ships. The dressing of the wounded went on continuously from 1.30 to 3.45—over two hours—the two medical officers of the *Varyag* and three from neutral men-of-war rendering first aid, examining wounds and removing foreign bodies that were easily got at, cleaning, protecting, and fixing injured parts, and administering stimulants or hypodermic injections of morphine. In that way about 60 wounded were attended to—the remainder not presenting themselves till subsequently. Nothing beyond first aid was attempted, nor was it possible. There had been two surgical stations, but the after one had been abandoned owing to a fire in the vicinity, so that the forward one was very crowded with wounded. It was also wet owing to the water from the fire-hoses and dark from the failure of the electric light. It was situated on the main deck near the sick-bay quarters. All the instruments had been laid out but those belonging to pocket cases were mainly employed. The wounded had been moved in the intervals of the action. Canvas stretchers and man-handling were employed in taking them to the bases. There was no special appliance for getting cases from the fighting tops. The ship being in a sinking condition had to be abandoned. Taking a modern armoured cruiser of the *Drake* class, where the casemates and barbettes formed the main protection for the fighting material and the side armour and protective deck the main protection to the explosive and propulsive material, and knowing that there were no places behind or below the latter where surgical stations could be established, it was to the shelter of the casemates assisted by the armoured transverse screens that some shelter for surgical stations was looked for. The surgical stations were likely to find most shelter and quiet on the main deck in the vicinity of the casemates. Those who fell on the upper deck and in the barbettes and upper deck casemates must remain there to await the arrival, in the lull of the action, of competent ambulance parties. There would probably be a sufficient proportion of cases able to walk who would keep the stations busy during the heat of the action. There should be two principal surgical stations on the main deck, one forward and one aft, subdivided port and starboard under protection of forward and after casemates and transverse screens; and the material furnishing these should be so simple that it would be easy to move through the armoured screen door to the next group of casemates and so fore and aft to have planned-out places for receiving wounded on either side. The medical staff should be proportioned equally to the fore and aft main surgical stations. Ladder ways on board ship were difficult to negotiate but if a transverse hand-bar was fixed across the extreme ends of the stretcher handles the process of lowering from the upper to the main deck was greatly facilitated. It was too short a distance to need special slings or slides. There had to be a chair or its like for slinging men from the tops when such were manned and a special means of transport out of the narrow and tortuous engine-room spaces and ammunition-supply platforms in case of need. A cruiser after an action should be cleared at once of wounded if she was to be serviceable, for the crew would want all the available space to rest and to reorganise in. If she could not proceed at once to a near base to renew men and material a hospital ship was urgently needed to receive the sick and wounded. Only major operations of the most pressing kind should be attempted on board and the instruments and spare dressings should be preserved below for that purpose. Advanced first-aid treatment should be combined with intelligent collection and distribution of wounded in a modern cruiser engagement. The sooner the enemy's fire was subdued the fewer would be the casualties. Therefore as regarded the wounded the captains of the guns must not have their primary duties interfered with by devoting any of their time to tourniquets and dressing bags. With regard to collection it was not expedient to risk the services of ambulance parties during any part of the fighting. In regard to distribution there ought to be one hospital ship in attendance on every six battleships and every eight first- or second-class cruisers.

Fleet Surgeon A. J. J. JOHNSTON, R.N., considered that in the construction of ships some place should be specially built for the reception of the wounded, well lighted and ventilated, and where operations could be performed.

Fleet Surgeon E. J. BIDEN, R.N. (retired), communicated a paper entitled

Remarks and Suggestions on the Head Dress of Certain Ratings in His Majesty's Fleet.

He discussed the question of the head covering of certain ratings in His Majesty's fleet with special reference to service in the tropics. He referred particularly to the artificer class, including the engine-room artificers, master-at-arms, and ship's corporals, sick berth staff, writers, stewards, and domestics. These men had a blue cloth peaked cap with a white linen cap-cover in the tropics. These men might be seen on shore on duty or on leave at Malta, Singapore, Hong-Kong, and such places with that very poor protection from the sun. It was a question how far that imperfect protection from the sun was responsible for sickness among the men. The health of the navy for 1903 gave 172 cases of heat-stroke in the total force but it was probable that the greater number of these were not sun-stroke but cases of heat-stroke amongst engine-room ratings. The seaman's straw hat might be much more extensively worn; it was comparatively cheap, light (weighing only 10 ounces), durable, and serviceable, being an efficient protection from sun or rain (especially with the brim turned down), it could be easily stowed away, and was smart in appearance.

Fleet Surgeon J. LLOYD THOMAS, R.N., urged the adoption of a thick hat of felt with a wide brim which was readily stowed away and, being pliable, could be turned down over the face, at the sides, or over the nape of the neck as occasion required.

Fleet Surgeon BEADNELL, R.N., communicated a paper on

Some Dynamic and Hydro-dynamic Effects of Modern Small-bore Cylindro-conoidal Projectiles.

He pointed out that the actual work capable of being done by the modern small-bore bullet upon the animal economy was from 1800 foot-pounds to 2800 foot-pounds. The cylindro-conoidal projectile, revolving about its major axis, advanced through the resisting atmosphere with that axis parallel to a tangent to the trajectory at the muzzle. Deformation, which might be due to "stripping," ricochet, or impact with resisting tissues, had the double effect of enlarging the impact area and prolonging the projectile's duration of action. In perforating the tissues the projectile acted like a hammer, driving particles in front of it like a wedge, displacing them laterally, and like a gimlet communicating a part of its rotary motion to them and hurling them into the surrounding tissues like drops of water off a mop. The so-called "explosive" effects were due to sudden enlargement of the impact area resulting from a modification either in the form or motion of the projectile. Many of the "explosive" phenomena were due to such eccentricities of flight as the various "spinning-top" and "pirouetting" motions of the projectile. Surrounding the orifice of ingress, which was circular and smaller in diameter than the projectile, was a white rim, visible at the extreme edges and due to removal by friction of superficial layers of the epidermis. From that orifice radiated minute fissures and if the introverted sectors between those fissures were examined they would be found to have lost their extreme tips. The size of the entrance aperture increased with the range and with the degree of laxity of the epidermis. Ecchymosis around the entrance aperture increased with the range; at extreme ranges there might be extensive bruising but no solution of continuity of the skin. The bullet track was usually the shortest distance between the apertures of entrance and exit; its transverse diameter was smaller than that of the projectile. The aperture of egress was equal to, or slightly exceeded, that of ingress; its sectors were everted and showed no loss of substance except in the case of very high velocities. The entrance aperture was occasionally, and the exit aperture frequently, multiple. The "flat" and "square" bones and the extremities of the larger "long" bones were neatly perforated. The diaphyses might be tunnelled but were more frequently fractured; in the latter case minute comminution together with dispersal of numerous "splinterettes" to a considerable distance occurred when velocity was very high; when it was lower the splinters were larger, less numerous, and closer to the fracture. Many instances were on record of partial or complete recovery after bullet perforations of both cerebral hemispheres. As the bullet entered the cranial space intracranial pressure rose and cerebro-spinal fluid and blood were expelled through the basal foramina. In gunshot wounds of the head brain matter might protrude from both the ingress and egress apertures. After the brief compression of the brain by the projectile there was an increase of bulk due to œdema, which aggravated the cerebral herniæ through the bullet orifices. He had never seen brain protruding through an orifice of ingress where death was instantaneous. Lateral pressures of the brain were liable to cause death through a mechanical lesion of the respiratory centre, though the heart continued to beat; hence in certain cases of gunshot wounds of the head it was not impossible that death might be averted by timely artificial respiration. Fracture of the orbital plate accompanied by complete proptosis of the eyeball was not uncommon after bullet perforations of the frontal lobe. Organs like the stomach, the bladder, and the intestines were grievously injured and their contents were scattered far and wide if fluid were present in any quantity; if empty, however, minute apertures were produced which closed immediately after the passage of the bullet and healed by first intention, thus preventing peritoneal infection. The possibility of more than one coil having been perforated had to be borne in mind in bullet lesions of the intestines. The power of the bullet at close ranges to "drag" its own wad into the depths of the tissues and at long ranges to force in particles of clothing was a factor not to be overlooked in connexion with deep suppuration of the bullet track. Owing to the extremely short contact-time of the modern projectile (about $\frac{1}{3000}$th of a second) the pain consequent upon the actual perforation was often absent, and even so large a region as the thorax might be completely perforated without the person being aware, at the time, of the fact. Local anæsthesia of the bullet track, especially at its entrance extremity, was another characteristic of wounds caused by the modern bullet. External hæmorrhage from the apertures was usually very slight; severe internal hæmorrhage, however, was not uncommon, as the modern small-bore bullet punched holes in the vessels instead of pushing them aside or cutting them completely across as was the custom of the larger, less energetic, and more obtuse-headed bullets in former use.

THURSDAY, JULY 27TH.

Lieutenant-Colonel H. J. BARNES, R.A.M.C. (secretary of the St. Andrew's Ambulance Association), read a paper on

Voluntary Ambulance Wagon Service for Cities.

He suggested that for both the City and County of London an ambulance wagon service should be provided and maintained by voluntary effort on the part of the community. That such a voluntary provision was quite practicable was shown by the continued existence of the accident transport service organised in Scotland by the St. Andrew's Ambulance Association. That was started in Glasgow so long ago as April, 1882, and the total number of patients conveyed since the formation of the service was 64,427 up to May 31st, 1904. The purchase and upkeep of these wagons, hiring of horses and drivers, and the wages of the trained attendants were all defrayed by voluntary public subscriptions; during the year not a single instance of complaint as to the service was made and no case occurred to which attention was not paid. There was some room for improvement in the means of telephonic communication during the small hours of the night, as the street fire alarms were not at present available for the purpose of calling the ambulance, but there were telephones available for the purpose, principally those at police stations, cab offices, shipping offices at the docks, engineering works, and other places open all night. The use of the wagons in cases of accident was absolutely free; cases of sudden illness occurring in the streets or public places were also included in the term "accident." Besides its use in accidents the accident transport service was largely employed by medical practitioners for the removal of cases of non infectious illness to the hospitals for operation, &c. For that, where patients could afford it, a small charge was made. Over-elaboration of the details in equipping an ambulance wagon was to be deprecated, as the simpler and less complicated the fittings the less risk there was of waste of time by their getting out of order and the easier it was to keep the wagon clean and aseptic. The same principle was followed in attending to sufferers—it was not sought to do too much. For instance, the attendants applied the very simplest first-aid dressing to a wound and otherwise interfered with it as little as possible, as the time was so short between an accident being sustained and the arrival at the hospital. Five wagons were kept for the Glasgow transport service and six wagon attendants. The average cost per turn out, including wages, uniforms, telephones, depreciation, insurance, horsing, storing and repairs, and a proportion of the head office rent, &c., was 8s. 2d. The only wagon services in England were those of Accrington, where there was one wagon entirely free to all cases, and Ipswich, where there were two wagons; both were maintained by public subscriptions under the auspices of the local centres of the St. John Ambulance Association and appea satisfaction. Indeed, it would seem that ambulance wagon service was dependent support of the public was a guarantee possible would be given, as otherwise not be forthcoming. In one supported out of the rates there was a risk of its becoming too "official" and not so sensitive to criticism. The efforts of the Metropolitan Street Ambulance Association would have been more usefully directed towards the establishment of an ambulance wagon service for London maintained by voluntary public subscriptions than in inducing the County Council to undertake such provision out of the rates. There should have been no difficulty in interesting the public in such a scheme if it was properly put before them. With regard to London, there were about 11,600 accidents yearly in workshops and factories there in addition to 10,000 street accidents and any scheme to be in any way complete must take account of the former as well as of the latter. Estimating on the experience of Glasgow and allowing for the greater acreage in London it would require at least 120 horse-drawn wagons to do it efficiently. Motor-driven ambulances might possibly reduce that number to 100, the saving in time being so great.

Surgeon-Major G. A. HUTTON said that it must be left for each town and city to adopt such system as would best suit their needs and requirements.

Captain W. PEMBERTON PEAKE, R.A.M.C. (Vol.), said that voluntary transport depended on the subscriptions of the charitable and there was a possibility of the subscriptions falling off and the work being disorganised in consequence.

Lieutenant-Colonel BARNES said that the voluntary system had not fallen away in Scotland but had lasted for 22 years. Free transport for accidents was defensible but the advisability of further pauperising the population by giving free removal in any case of sickness was very doubtful.

Dr. E. L. JENKINS (late civil surgeon to His Majesty's forces in South Africa, 1900-02) communicated a paper on

The Causation, Varieties, and Treatment of Dysentery on Active Service.

He said that overcrowding, which seemed to be a natural sequence of camp life, was an important cause of dysentery. Other factors, however, operated in conjunction with overcrowding and whenever there was a scarcity of food and its quality was open to suspicion the incidence of dysentery became far greater. During active service additional factors played an important rôle, conditions which reduced the vitality of the system and thus rendered soldiers more vulnerable to the disease. Among those were exposure to alternating periods of heat and cold, bodily exhaustion, lying on damp ground, as well as the mental anxiety incidental to a campaign. There were other conditions which more directly determined infection, such as the pollution of soil and water by fæcal material. Dysentery showed a partiality for the warmer climates, while its frequency and severity tended to increase as the equator was neared. Recognising, then, the infectious nature of the disease it was most important that all dysenteric stools should be properly disinfected and either deeply buried at a distance or cremated. The most important factors in the treatment of all forms of dysentery were rest and diet. The patient should be strictly confined to bed throughout the attack, whether mild or severe. Any movement in bed was to be avoided as much as possible, so the bed-pan must be used to obviate the necessity of getting up to stool. Fresh milk, if obtainable, was always the best form of food and about three to four pints might be given during the 24 hours, in small quantities at a time and at frequent intervals. In the absence of fresh milk condensed milk might be substituted, whilst beef-tea, chicken soup, and certain meat essences proved valuable adjuncts. If ordinary milk was not well digested it might be peptonised or diluted with either lime or barley water. Any liquid food was best given in a lukewarm state, as cold liquids by stimulating peristaltic action tended to aggravate the disease. The first indication was to relieve pain and tenesmus in acute cases, and there was no better remedy than the old-fashioned enema of starch and opium, each enema consisting of half a drachm of tincture of opium, made up with an ounce of starch mucilage. The greatest possible care was required during its administration on account der and sensitive nature of the large bowel. often found much relief from the application of steeped in a liniment of opium applied to the abdominal surface, while hot water bottles to the feet and sufficient blankets to insure bodily warmth constituted an essential part of the treatment. They were next confronted with the necessity of removing foul accumulations in contact with the ulcerated mucous membrane. That might be done by giving gently acting aperients, as half an ounce of sulphate of sodium every hour until copious motions resulted. Another method was the internal administration of antiseptics, but prior to giving any such drugs it was necessary to allay both tenesmus and pain by the free use of opium. Ipecacuanha curtailed the course of the disease in many cases but, on the other hand, required careful use on account of its emetic action. It should be given on an empty stomach and as that drug was much tolerated in dysentery a dose of about 30 grains of the powder was necessary every four to six hours until the motion became yellow and less slimy. Once the acute stage was passed and the digestive powers returned the patient's strength might be well maintained and such additional support as eggs and finely divided raw meat might be allowed. The stage of convalescence being well established, tonics became useful, and to accomplish the necessary improvement in health a sea voyage or change of climate was necessary.

Major N. FAICHNIE, R.A.M.C., contributed a paper on the

Varieties, Causation, and Treatment of Dysentery in the Field.

He said that dysentery might be defined as a disease marked by frequent bloody and mucous stools, fever, tenesmus and griping, together with thickening and ulceration of the mucous and submucous coats of the large intestine. As the cæcum or rectum was most affected, griping and tenesmus respectively were the most prominent symptoms. Dysentery might be: 1. Endemic or amœbic. 2. Sporadic, due to mechanical irritation. In South Africa he had seen several cases of that variety, due to the carrots in the rations; with those men slices of carrots were seen in the stools, so that the ileo-colitis produced was the result of want of mastication. 3. Epidemic or bacillary. That was the commonest form occurring in the field and his remarks were limited to that form. Epidemic dysentery was probably due to a group of bacilli, the dysenteric and paradysenteric, which were allied to each other and to the bacillus coli, their cultural differences being mainly due to the reactions of the sugars. The disease might be contracted: (1) from impure water; (2) from dust carried about by the wind; (3) from infection by flies; (4) from want of personal cleanliness, especially as regarded hands and clothes: and (5) from infection from latrines and seats if there were any. That impure water was not the only cause was shown by the fact that when nothing but tea or boiled water was drunk dysentery still occurred. Treatment was: 1. Preventive. (*a*) Patients suffering from diarrhœa and dysentery should be made to report sick at once so as to prevent the fouling of camps; (*b*) all cases of dysentery should be at once isolated so that their stools might be disinfected; (*c*) latrines should be carefully covered with earth and, if possible, sprinkled with chloride of lime so that the spread of infection by dust and flies might be stopped; and (*d*) before rejoining patients should be made to bathe if possible and their clothes should be disinfected or replaced. 2. Removal from the field. Mild cases might get well in a few days and might be allowed to rejoin their units but more severe cases should be sent to the base or the lines of communication as soon as possible. Patients kept moving about were extremely liable to relapses and were also a source of further infection. 3. Medicinal. Cases varied so much that it was difficult to lay down definite rules. Rest and an equable temperature were essential always. For acute cases the best treatment was that by sulphate of sodium or magnesium: that should be given in as concentrated a form as possible and lukewarm. At first drachm doses might be given every hour till the stools contained fæcal matter and then the interval between the doses increased. When there was no more blood or mucus perchloride of mercury in 45 minim doses with tinctura chloroformi et morphinæ every four hours should be substituted. Bismuth and opium and sulphur and opium were also useful at that stage to stop the diarrhœa. When there was much tenesmus a starch and opium enema gave relief. The earlier the treatment by the sulphates was commenced the more chance was there of its being successful. In chronic cases he did not think sulphate of magnesium was of use. A dose of castor oil might be given occasionally, followed by bismuth or sulphur and opium; if hæmorrhage was very severe oleum terebinthinæ was sometimes useful in checking it. It was when dysentery became chronic that local treatment by the bowel proved most useful. A soft rubber tube might be inserted for 20 inches into the rectum, cocaine ointment having first been employed at the anus. A solution of bicarbonate of sodium, 60 grains to the pint, followed by two or three pints of a solution of tincture of iodine once or twice a day, gave beneficial results. 4. Diet. One of the most important points in the treatment of dysentery was the diet. All food should be given lukewarm, neither hot nor cold. In mild cases milk might be suitable but frequently it was not so. In all except the mildest cases whey or albumin water was far preferable to milk and while the symptoms were acute a total of two or three pints at the most of liquid nourishment in the 24 hours was quite sufficient. When fresh milk and eggs were not obtainable tinned milk had hitherto generally been the only food available. That often produced nausea and vomiting and, in consequence, not only exhaustion but in some cases starvation. In severe cases of dysentery, even if nausea was not produced, tinned milk was therefore not suitable any more than fresh when the latter was available. The question of finding substitutes practicable for use in the field then became an important matter. For that purpose Major Faichnie suggested two—viz, whey and plasmon. 1. Whey. It should be remembered that whey could not be satisfactorily made from tinned milk either by fresh rennet or by rennet tabloid. What could be used for the purpose, however, was alum. If one pint of sweetened or unsweetened milk be heated to 150° F. and 20 or 40 grains of alum be added a milky or pure whey respectively could be obtained; thus, one ounce of dry alum was sufficient to curdle thoroughly ten pints of milk and the resulting whey had no taste of the alum and could be flavoured by lemon or orange or coffee essence if desired. 2. Plasmon. That could be used by boiling one and a half ounces of the dry powder with water to make stock; this, mixed with one and a half pints of barley-water and flavoured as before mentioned, would serve as sufficient nutriment for 24 hours or, instead, by simply whipping and flavouring, half the plasmon stock could be made into plasmon sponge cream and could be given alternately with the plasmon and barley-water beverage. A supply of alum and plasmon should be included in the supplies of the field ambulances for the future. There was no doubt in his mind of the great value in dysentery of digitalis and yet neither in books on materia medica nor in those on tropical medicine had he seen any mention made of the use of that drug in that disease. Alcohol, in his opinion, did not compare with digitalis as a cardiac tonic and stimulant and in dysentery alcohol aggravated the symptoms; therefore the use of digitalis was an extremely important matter, not only on ordinary occasions but especially in the field where so many dysenteric patients might die from exhaustion.

Surgeon-Lieutenant-Colonel G. S. ROBINSON (Scots Guards) (retired) said that the freedom of the Japanese from dysentery was attributed to sanitation, but it was more probably due to their simple diet. The causes in relative importance were chill, water, and food.

Major J. B. BUCHANAN, R.A.M.C., said that the great difficulty of treating dysentery in war at the front was the fact that the patient was always on the move and often did not reach a stationary hospital for ten days or more, during which time it was difficult to carry out a suitable treatment by sulphate of magnesium or ipecacuanha.

Major FAICHNIE said that however important pure water might be they should look for additional causes for dysentery.

Major W. M. O'CONNOR, R.A.M.C. (Militia), read a paper on

The Military Medical Reserve Difficulty.

He said that the late war showed how important it was to be ready as it would be remembered that the War Office had to employ in South Africa alone between 400 and 500 civil surgeons and a large number of orderlies taken from various volunteer societies, such as St. John Ambulance Association, and it could not be said that they were altogether satisfactory. It would seem in time of war that there were three methods to choose from. The first was to keep the Royal Army Medical Corps up to war establishment, which would then, of course, necessitate a smaller reserve in time of war. The second was to have a large reserve of civil surgeons and orderlies from St. John Ambulance Association and kindred societies. The third was by encouraging the formation of a home or limited medical service, offering inducements to the best men of the profession to accept commissions. The first method was too expensive and the second was not one that could be encouraged, as it had been however, minute apertures were produced which closed immediately after the passage of the bullet and healed by first intention, thus preventing peritoneal infection. The possibility of more than one coil having been perforated had to be borne in mind in bullet lesions of the intestines The power of the bullet at close ranges to "drag" its own wad into the depths of the tissues and at long ranges to force in particles of clothing was a factor not to be overlooked in connexion with deep suppuration of the bullet track. Owing to the extremely short contact-time of the modern projectile (about $\frac{1}{3000}$th of a second) the pain consequent upon the actual perforation was often absent, and even so large a region as the thorax might be completely perforated without the person being aware, at the time, of the fact. Local anæsthesia of the bullet track, especially at its entrance extremity, was another characteristic of wounds caused by the modern bullet. External hæmorrhage from the apertures was usually very slight; severe internal hæmorrhage, however, was not uncommon, as the modern small-bore bullet punched holes in the vessels instead of pushing them aside or cutting them completely across as was the custom of the larger, less energetic, and more obtuse-headed bullets in former use.

THURSDAY, JULY 27TH.

Lieutenant-Colonel H. J. BARNES, R.A.M.C. (secretary of the St. Andrew's Ambulance Association), read a paper on

Voluntary Ambulance Wagon Service for Cities.

He suggested that for both the City and County of London an ambulance wagon service should be provided and maintained by voluntary effort on the part of the community. That such a voluntary provision was quite practicable was shown by the continued existence of the accident transport service organised in Scotland by the St. Andrew's Ambulance Association. That was started in Glasgow so long ago as April, 1882, and the total number of patients conveyed since the formation of the service was 64,427 up to May 31st, 1904. The purchase and upkeep of these wagons, hiring of horses and drivers, and the wages of the trained attendants were all defrayed by voluntary public subscriptions: during the year not a single instance of complaint as to the service was made and no case occurred to which attention was not paid. There was some room for improvement in the means of telephonic communication during the small hours of the night, as the street fire alarms were not at present available for the purpose of calling the ambulance, but there were telephones available for the purpose, principally those at police stations, cab offices, shipping offices at the docks, engineering works, and other places open all night. The use of the wagons in cases of accident was absolutely free; cases of sudden illness occurring in the streets or public places were also included in the term "accident." Besides its use in accidents the accident transport service was largely employed by medical practitioners for the removal of cases of non infectious illness to the hospitals for operation, &c. For that, where patients could afford it, a small charge was made. Over-elaboration of the details in equipping an ambulance wagon was to be deprecated, as the simpler and less complicated the fittings the less risk there was of waste of time by their getting out of order and the easier it was to keep the wagon clean and aseptic. The same principle was followed in attending to sufferers—it was not sought to do too much. For instance, the attendants applied the very simplest first-aid dressing to a wound and otherwise interfered with it as little as possible, as the time was so short between an accident being sustained and the arrival at the hospital. Five wagons were kept for the Glasgow transport service and six wagon attendants. The average cost per turn out, including wages, uniforms, telephones, depreciation, insurance, horsing, storing and repairs, and a proportion of the head office expenses of management, rent, &c., was 8*s*. 2*d*. The only purely voluntary ambulance wagon services in England were those of Accrington, where there was one wagon entirely free to all cases, and Ipswich, where there were two wagons; both were maintained by public subscriptions under the auspices of the
St. John Ambulance Association and a
satisfaction. Indeed, it would seem t
ambulance wagon service was depende
support of the public was a guarantee
possible would be given, as otherwise

not be forthcoming. In one supported out of the rates there was a risk of its becoming too "official" and not so sensitive to criticism. The efforts of the Metropolitan Street Ambulance Association would have been more usefully directed towards the establishment of an ambulance wagon service for London maintained by voluntary public subscriptions than in inducing the County Council to undertake such provision out of the rates. There should have been no difficulty in interesting the public in such a scheme if it was properly put before them. With regard to London, there were about 11,600 accidents yearly in workshops and factories there in addition to 10,000 street accidents and any scheme to be in any way complete must take account of the former as well as of the latter. Estimating on the experience of Glasgow and allowing for the greater acreage in London it would require at least 120 horse-drawn wagons to do it efficiently. Motor-driven ambulances might possibly reduce that number to 100, the saving in time being so great.

Surgeon-Major G. A HUTTON said that it must be left for each town and city to adopt such system as would best suit their needs and requirements.

Captain W. PEMBERTON PEAKE, R A.M.C (Vol), said that voluntary transport depended on the subscriptions of the charitable and there was a possibility of the subscriptions falling off and the work being disorganised in consequence.

Lieutenant-Colonel BARNES said that the voluntary system had not fallen away in Scotland but had lasted for 22 years. Free transport for accidents was defensible but the advisability of further pauperising the population by giving free removal in any case of sickness was very doubtful.

Dr. E. L. JENKINS (late civil surgeon to His Majesty's forces in South Africa, 1900–02) communicated a paper on

The Causation, Varieties, and Treatment of Dysentery on Active Service.

He said that overcrowding, which seemed to be a natural sequence of camp life, was an important cause of dysentery. Other factors, however, operated in conjunction with overcrowding and whenever there was a scarcity of food and its quality was open to suspicion the incidence of dysentery became far greater. During active service additional factors played an important rôle, conditions which reduced the vitality of the system and thus rendered soldiers more vulnerable to the disease. Among those were exposure to alternating periods of heat and cold, bodily exhaustion, lying on damp ground, as well as the mental anxiety incidental to a campaign. There were other conditions which more directly determined infection, such as the pollution of soil and water by fæcal material. Dysentery showed a partiality for the warmer climates, while its frequency and severity tended to increase as the equator was neared. Recognising, then, the infectious nature of the disease it was most important that all dysenteric stools should be properly disinfected and either deeply buried at a distance or cremated. The most important factors in the treatment of all forms of dysentery were rest and diet. The patient should be strictly confined to bed throughout the attack, whether mild or severe. Any movement in bed was to be avoided as much as possible, so the bed-pan must be used to obviate the necessity of getting up to stool. Fresh milk, if obtainable, was always the best form of food and about three to four pints might be given during the 24 hours, in small quantities at a time and at frequent intervals. In the absence of fresh milk condensed milk might be substituted, whilst beef-tea, chicken soup, and certain meat essences proved valuable adjuncts. If ordinary milk was not well digested it might be peptonised or diluted with either lime or barley water. Any liquid food was best given in a lukewarm state, as cold liquids by stimulating peristaltic action tended to aggravate the disease. The first indication was to relieve pain and tenesmus in acute cases, and there was no better remedy than the old-fashioned enema of starch and opium, each enema consisting of half a drachm of tincture of opium, made up with an ounce of starch mucilage. The greatest possible
was required during its administration on account
nature of the large bowel.
elief from the application of
nent of opium applied to the
water bottles to the feet and
odily warmth constituted an

essential part of the treatment. They were next confronted with the necessity of removing foul accumulations in contact with the ulcerated mucous membrane. That might be done by giving gently acting aperients, as half an ounce of sulphate of sodium every hour until copious motions resulted. Another method was the internal administration of antiseptics, but prior to giving any such drugs it was necessary to allay both tenesmus and pain by the free use of opium. Ipecacuanha curtailed the course of the disease in many cases but, on the other hand, required careful use on account of its emetic action. It should be given on an empty stomach and as that drug was much tolerated in dysentery a dose of about 30 grains of the powder was necessary every four to six hours until the motion became yellow and less slimy. Once the acute stage was passed and the digestive powers returned the patient's strength might be well maintained and such additional support as eggs and finely divided raw meat might be allowed. The stage of convalescence being well established, tonics became useful, and to accomplish the necessary improvement in health a sea voyage or change of climate was necessary.

Major N. FAICHNIE, R.A.M.C., contributed a paper on the

Varieties, Causation, and Treatment of Dysentery in the Field.

He said that dysentery might be defined as a disease marked by frequent bloody and mucous stools, fever, tenesmus and griping, together with thickening and ulceration of the mucous and submucous coats of the large intestine. As the cæcum or rectum was most affected, griping and tenesmus respectively were the most prominent symptoms. Dysentery might be: 1. Endemic or amœbic. 2. Sporadic, due to mechanical irritation. In South Africa he had seen several cases of that variety, due to the carrots in the rations; with those men slices of carrots were seen in the stools, so that the ileo-colitis produced was the result of want of mastication. 3. Epidemic or bacillary. That was the commonest form occurring in the field and his remarks were limited to that form. Epidemic dysentery was probably due to a group of bacilli, the dysenteric and paradysenteric, which were allied to each other and to the bacillus coli, their cultural differences being mainly due to the reactions of the sugars. The disease might be contracted: (1) from impure water; (2) from dust carried about by the wind; (3) from infection by flies; (4) from want of personal cleanliness, especially as regarded hands and clothes; and (5) from infection from latrines and seats if there were any. That impure water was not the only cause was shown by the fact that when nothing but tea or boiled water was drunk dysentery still occurred. Treatment was: 1. Preventive. (*a*) Patients suffering from diarrhœa and dysentery should be made to report sick at once so as to prevent the fouling of camps; (*b*) all cases of dysentery should be at once isolated so that their stools might be disinfected; (*c*) latrines should be carefully covered with earth and, if possible, sprinkled with chloride of lime so that the spread of infection by dust and flies might be stopped; and (*d*) before rejoining patients should be made to bathe if possible and their clothes should be disinfected or replaced. 2. Removal from the field. Mild cases might get well in a few days and might be allowed to rejoin their units but more severe cases should be sent to the base or the lines of communication as soon as possible. Patients kept moving about were extremely liable to relapses and were also a source of further infection. 3. Medicinal. Cases varied so much that it was difficult to lay down definite rules. Rest and an equable temperature were essential always. For acute cases the best treatment was that by sulphate of sodium or magnesium: that should be given in as concentrated a form as possible and lukewarm. At first drachm doses might be given every hour till the stools contained fæcal matter and then the interval between the doses increased. When there was no more blood or mucus perchloride of mercury in 45 minim doses with tinctura chloroformi et morphinæ every four hours should be substituted. Bismuth and opium and sulphur and opium were also useful at that stage to stop the diarrhœa. When there was much tenesmus a starch and opium enema gave relief. The earlier the treatment by the sulphates was commenced the more chance was there of its being successful. In chronic cases he did not think sulphate of magnesium was of use. A dose of castor oil might be given occasionally, followed by bismuth or sulphur and opium; if hæmorrhage was very severe oleum terebinthinæ was sometimes useful in checking it. It was when dysentery became chronic that local treatment by the bowel proved most useful. A soft rubber tube might be inserted for 20 inches into the rectum, cocaine ointment having first been employed at the anus. A solution of bicarbonate of sodium, 60 grains to the pint, followed by two or three pints of a solution of tincture of iodine once or twice a day, gave beneficial results. 4. Diet. One of the most important points in the treatment of dysentery was the diet. All food should be given lukewarm, neither hot nor cold. In mild cases milk might be suitable but frequently it was not so. In all except the mildest cases whey or albumin water was far preferable to milk and while the symptoms were acute a total of two or three pints at the most of liquid nourishment in the 24 hours was quite sufficient. When fresh milk and eggs were not obtainable tinned milk had hitherto generally been the only food available. That often produced nausea and vomiting and, in consequence, not only exhaustion but in some cases starvation. In severe cases of dysentery, even if nausea was not produced, tinned milk was therefore not suitable any more than fresh when the latter was available. The question of finding substitutes practicable for use in the field then became an important matter. For that purpose Major Faichnie suggested two—viz., whey and plasmon. 1. Whey. It should be remembered that whey could not be satisfactorily made from tinned milk either by fresh rennet or by rennet tabloid. What could be used for the purpose, however, was alum. If one pint of sweetened or unsweetened milk be heated to 150° F. and 20 or 40 grains of alum be added a milky or pure whey respectively could be obtained; thus, one ounce of dry alum was sufficient to curdle thoroughly ten pints of milk and the resulting whey had no taste of the alum and could be flavoured by lemon or orange or coffee essence if desired. 2. Plasmon. That could be used by boiling one and a half ounces of the dry powder with water to make stock: this, mixed with one and a half pints of barley-water and flavoured as before mentioned, would serve as sufficient nutriment for 24 hours or, instead, by simply whipping and flavouring, half the plasmon stock could be made into plasmon sponge cream and could be given alternately with the plasmon and barley-water beverage. A supply of alum and plasmon should be included in the supplies of the field ambulances for the future. There was no doubt in his mind of the great value in dysentery of digitalis and yet neither in books on materia medica nor in those on tropical medicine had he seen any mention made of the use of that drug in that disease. Alcohol, in his opinion, did not compare with digitalis as a cardiac tonic and stimulant and in dysentery alcohol aggravated the symptoms; therefore the use of digitalis was an extremely important matter, not only on ordinary occasions but especially in the field where so many dysenteric patients might die from exhaustion.

Surgeon-Lieutenant-Colonel G. S. ROBINSON (Scots Guards) (retired) said that the freedom of the Japanese from dysentery was attributed to sanitation, but it was more probably due to their simple diet. The causes in relative importance were chill, water, and food.

Major J. B. BUCHANAN, R.A.M.C., said that the great difficulty of treating dysentery in war at the front was the fact that the patient was always on the move and often did not reach a stationary hospital for ten days or more, during which time it was difficult to carry out a suitable treatment by sulphate of magnesium or ipecacuanha.

Major FAICHNIE said that however important pure water might be they should look for additional causes for dysentery.

Major W. M. O'CONNOR, R.A.M.C. (Militia), read a paper on

The Military Medical Reserve Difficulty.

He said that the late war showed how important it was to be ready as it would be remembered that the War Office had to employ in South Africa alone between 400 and 500 civil surgeons and a large number of orderlies taken from various volunteer societies, such as St. John Ambulance Association, and it could not be said that they were altogether satisfactory. It would seem in time of war that there were three methods to choose from. The first was to keep the Royal Army Medical Corps up to war establishment, which would then, of course, necessitate a smaller reserve in time of war. The second was to have a large reserve of civil surgeons and orderlies from St. John Ambulance Association and kindred societies. The third was by encouraging the formation of a home or limited medical service, offering inducements to the best men of the profession to accept commissions. The first method was too expensive and the second was not one that could be encouraged, as it had been distinctly shown that a military training and a knowledge of military details were necessary in the army. The third method, and the only possible sound solution of the difficulty, was to have a thoroughly efficient and sufficient body of medical men and orderlies for small as well as great wars. It had been proposed to form a general service and a limited medical service, the officers and men of the former corresponding to the present Royal Army Medical Corps, who should receive good pay and allowances on account of the foreign service they would undertake. In Germany, Russia, Switzerland, Sweden, and other European States they had the most skilled and famous surgeons in the army. In peace time those surgeons were, in addition to their military duties, allowed to continue their private work in the neighbourhood of their military charge and thus those States could afford to employ a very large number of medical men in time of peace and so had a large body always ready for war. Great Britain could not very well act altogether like these States on account of the colonies and it was therefore necessary that there should be a well-paid and attractive foreign medical service, but if that home medical service were formed giving less emoluments and smaller pensions but allowing the officers to continue their private work as in the Indian Medical Service and in the countries named, there would be no difficulty, just as there was none in those same countries, in forming a very large body of military medical men, including the very best men in the profession, who in time of emergency also would be liable for service anywhere. These officers would be attached to home service battalions—in fact, their own territorial regiments if possible—and the auxiliary medical service would be absorbed under that new scheme. Their pay and pension would not be out of proportion to their services, as patriotism—and glory if they liked—should make them most willing to serve. To those who could not be given military duty, as their residence might make it impossible, Major O'Connor would give a retaining grant of £25 a year in addition to the pay of their rank during training or while serving.

Surgeon-Lieutenant-Colonel ROBINSON suggested that if the Army Medical Reserve were to be employed more freely in time of peace they might be used to train a reserve of men in nursing duties.

FRIDAY, JULY 28TH.

Surgeon-Lieutenant-Colonel ROBINSON read a paper on

The Feeding of the Soldier on Active Service.

He said that as to the food itself the quantity laid down was ample and during the recent war it was generally of good quality. Bread, however, should be issued whenever possible. It was such an important article of diet that men missed it greatly and would do anything to obtain it. Other nations appeared to attach great importance to it. A portable bakery should accompany troops and be made use of at every opportunity. A great deal had been written on the subject of drinking water, the difficulty being that men when thirsty would drink the water most accessible, no matter what its quality. The first thing to be done was to let the soldier realise that the constant drinking of tepid and dirty water was not only injurious but failed to relieve thirst. It was, however, to the cooking they must look to get the most good out of the rations which were sufficient and to insure that variety which appeared to be essential to the well-being of man. On active service there was a lamentable monotony in the meals provided. The almost universal practice consisted of cutting the meat into chunks, filling the kettle with water, and stewing the whole for two hours. But no matter how excellent those stews might be, a roast or baked alternative seemed almost a necessity and that appeared at present unattainable. A large portable oven on wheels would be a great boon, not only for obtaining variety in cooking but also for baking bread. One great additional advantage would be that cooking could be started before the destination was reached and so much time would be saved. A man was not a fully trained soldier if he could not himself turn out something tasty in the way of a supper. That was a matter to which more importance might be attached during training, especially at manœuvres. The soldier was too much accustomed to come back to a "certain place" and there to find his dinner waiting him. In the earlier part of the war men on outpost or other duty away from their companies were half starved by not knowing how to cook their ration of meat and flour. On that subject a quartermaster-sergeant of Royal Artillery, who was three years in South Africa, writes as follows:—"I found as cooks we were absolutely of no use. Often in getting over the country we could, and did, pick up growing vegetables, which, when cooked in with the meat ration, would have made excellent soup and stew. But we seemed to depend too much on the one man who was the regimental cook, whose qualification for that post was often that he had bad feet for marching or was not too handy round a gun and so was appointed cook! The meal (dinner) always consisted of the 'stewed type,' chunks of meat thrown in the oval 12-quart camp kettle, immersed in water, and left to cook for two hours or so. When served up the very appearance of it proved sufficient and even hungry men would not eat it. I have seen whole kettles full which have never been touched, the men preferring their biscuit and jam. A man who could concoct a savoury meal out of the ration was rare indeed, and all were anxious to secure him as messmate. The Bushmen and New Zealanders could prepare a meal—i.e., coffee or tea, with steak, chop, liver, &c.—and be sitting down enjoying it whilst the British soldier was looking for wood or an axe to chop it with." In regard to field hospitals in all cases fresh meat should be obtainable for those sick who required it, on requisition by the medical officer. Special biscuit should also be obtainable for men suffering from fever or bowel complaint as they were quite unable to make use of ration biscuit. Those made from arrowroot or fine flour could often be used, or better still some kind of rusk which would make into "bread-and-milk." Rice, so easily prepared and digested, ought also to be forthcoming. "Ideal" (an unsweetened form of tinned milk) should be provided for those who could not take the sweeter forms of condensed milk. Unfortunately, it was rather more bulky owing to its being less condensed. For convalescents tinned chicken and rabbit were the most appreciated and most suitable diet. Tinned butter was a luxury but the sick expected to get something a little extra when in hospital. Small ovens were furnished to field hospitals. A great difficulty, however, during the late war was in getting cooks. A larger number of orderlies and other soldiers should be specially trained as cooks. That matter seemed to have been taken in hand by the authorities since the war as a special section of the corps was now made up of qualified cooks. The committee appointed to report on these matters said that it was very desirable that all soldiers should be systematically taught how to cook their rations in the field, especially men of the Army Medical Service and the auxiliary medical services. The committee also attached great importance to the careful instruction of company cooks in camp cooking and considered that a good deal of irritation of the bowel was caused by half cooked or badly cooked rations on service. The connexion between that "irritation of the bowel" and camp diarrhœa, colitis, dysentery, enteric fever, and cholera was a very close one; and if by careful training, cooking, and dieting the preliminary cause of that irritation could be done away with the saving to the army and State would be considerable and amply repay the trouble taken.

Fleet Surgeon A. J. J. JOHNSTON, R.N., suggested that every man should take his turn as cook, so that on active service everyone would be able to cook.

Lieutenant-Colonel E. M. WILSON, R.A.M.C. (retired), explained the arrangements that were made for the teaching of cooking in the Royal Army Medical Corps and hoped that a larger number might be instructed in that most useful service.

Surgeon-Lieutenant Colonel ROBINSON said that universal instruction in extemporised cooking could only be dealt with by serving out the rations to groups of men during manœuvres.

Surgeon-Lieutenant-Colonel P. B. GILES (Volunteers) read a paper on

The Care of Soldiers' Feet.

He said that in all cases of deficiently developed arch there was one cardinal object to attain—viz., to get the arch properly established and maintained. It mattered comparatively little in actual practical treatment whether the metatarso-phalangeal joints and the phalanges were prehensile or were lifting factors or a composition of both, so long as the fact was accepted that the foot should be flexible and not rigid in walking and marching. That the foot should be flexible and not rigid in marching was proved by the success which had attended cases of insufficiency of the arch when treated by employment of extra work upon the metatarso-phalangeal joints as compared with that of "blocking up" the foot and so creating a system of walking with a rigid foot. Excessive development of the arch with a small heel, associated as it always was with more or less eversion of the foot, was a matter of great difficulty to correct. He had rarely failed to make good walkers out of those with deficiencies of the arch under proper training, but he had never been really successful with an over-developed arch accompanied with a small heel. It was not so generally recognised that the acridness of the secretion of the feet was a predominating factor in sore feet and that those who were afflicted with that secretion not only blistered easily but developed soft corns of a most intractable form. In regard to the artificial covering of the feet socks must be thick, of wool, and have natural-shaped toes. Cotton socks were fatal; they were thin, non-elastic, very absorbent, and with moist feet soon became a veritable sponge. Wool, on the other hand, could be made thick, was elastic, and when covered with perspiration would, if exposed to the air and sun, quickly dry, could be beaten and well rubbed if washing was impossible, and come out daily fairly fresh. Rags, bandages, and felt were frequently vaunted over socks, but his experience and observation with troops were against all those wrappings when used with laced boots. In such cases where blucher or riding boots were used and the foot was more or less rigid wrapping as compared with socks was on a par or even better because the back of the heel could be better protected. Boots should be large enough to give freedom antero-posteriorly as well as laterally, without being loose. The soles should be thick, the waist pliable, and the heels large and low, but the *sine quâ non* was that the inside of the boot must be cut straight and coincide with Meyer's line and not turn up at the toe. The upper should be soft and there should be no harsh seam at the heels. After each march there should be an inspection of the feet for the first few days by the medical officer, after which by the company officers, only cases of doubt or those requiring treatment being sent to the medical officer. The routine washing followed by pickling in a solution of salt and boric acid rendered the most moist feet safe. That treatment was far in front of ointments or grease of any kind, as even when well fortified with antiseptics grease had a tendency at the heat of the body to ferment and to create the very mischief which the remedies were used to prevent. Soaped socks were seldom of service because the soap being generally of a common kind was either too fatty or contained a large proportion of alkali.

Captain PEAKE discussed the importance of properly fitting boots and declared that the shape of the boot was of the utmost importance to the mobility of an army.

Lieutenant-Colonel WILSON emphasised the importance of the subject and urged that men should not only be able to use their rifles but also to walk upon their feet.

Lieutenant-Colonel J. J. DE ZOUCHE MARSHALL, R.A.M.C. (Vol.), communicated a paper entitled

Suggestions for First-aid Treatment of Fractured Thigh in Military or Civil Practice.

He stated that the object of the paper was the simplification of first-aid treatment of the injured in connexion with fractured thigh whether in warfare or in civil life. The "rifle splint," providing as it did perfect counter-extension, had been looked upon by all acquainted with it as an ideal remedy in such cases, but he had learned from army medical officers with large experience in the South African war that it was very seldom used in that campaign owing to the terror produced in the minds of the unfortunate patients at the mere idea of its complicated application in the hands of imperfectly trained men, of whom, unfortunately, hundreds had to be employed there as stretcher bearers. From what he knew of the splendid training of the non-commissioned officers and men of the Royal Army Medical Corps he had no doubt that a squad of them could with ease and expedition apply a rifle splint with the minimum of suffering to a patient, but how often did it happen that a Royal Army Medical Corps squad could be kept together in South Africa? Instead it was doubtless necessary to place one Royal Army Medical Corps "trained" man in charge of three others of "all sorts" to make up squads and Tommy Atkins was just the man to diagnose at a glance whether such bearers were up to their work or not. Hence the yells and screams that dismissed the "rifle splint" and compelled the transport of those cases from the field on a stretcher with little more "dressing" than a bandage or two around the stretcher to steady the body on it. If that was the case with one well-trained and three partially trained men it was awful to contemplate the effects of the efforts of one partially trained civil ambulance man and three totally untrained men to apply a "broom handle" and other splints, with about seven bandages, to a case of fractured thigh occurring in one of our streets or factories and their unrehearsed struggles to get their patient on to a stretcher. For that was the most that civil ambulance teachers could hope for—viz., that one of their certificated pupils might happen to be on the scene of such an accident and that the said pupil might be able to direct the movements of a few untaught men from the crowd. It stood to reason that in either case, military or civil, the treatment taught and practised should be of the simplest nature consistent with efficiency. The treatment in vogue of securing a long splint with several bandages involved so many liftings of the body and limb that the process, undertaken by amateurs, must be attended by much suffering, for, though a gentle method of introducing bandages beneath the body and limb was sometimes taught, it was seldom put into practice even at civil ambulance examinations and would doubtless be forgotten altogether in the flurry of an actual accident. In considering an effective treatment not involving all that tying of bandages around the body and limb Lieutenant-Colonel Marshall evolved the idea of taking the stretcher as it was and relying for the fixation of the pelvis of the patient on a roller perineal bandage attached to the upper handles and for counter-extension on bandages fixed to the patient's foot and lower handles. For that stretcher first-aid treatment of fractured thigh he claimed that it could be carried out expeditiously and painlessly; that it placed the limb in the best position for dealing with hæmorrhage in a compound fracture and for subsequent permanent treatment in hospital; that it reduced to a minimum the suffering and danger during transport caused by sharp spiculæ of bone injuring nerves and blood-vessels; and that by fixing the patient on the stretcher it enabled him to be carried up or down steep hills and did away with the risk of his being thrown off in case either of the bearers should stumble while carrying him "shoulder high"—a proceeding in much favour with eminent military surgeons, notwithstanding the warnings against it in text-books.

PSYCHOLOGICAL MEDICINE.

FRIDAY, JULY 28TH.

Dr. ROBERT JONES (Claybury Asylum) opened a discussion on

Prognosis in Mental Diseases.

Prognosis meant generally to foretell, foreshow, forebode, to predict, presage, or to prophesy what was likely to take place and the ability implied a power of foretelling the future by the correct interpretation of present signs. Prognosis when applied according to the principles of medicine was the judgment formed by the physician regarding the future progress and termination of any disease. The fate of the patient caused particular anxiety to the relatives in cases of mental disease and questions were asked such as "Is there danger to life?" "Will the illness terminate in recovery or death?" "Is the illness likely to be a long-continued one?" and "Will there be any permanent mental weakness left behind after recovery from the attack?" It was of the utmost importance that a correct answer should be given, for the family might have to bear the burden of the care and treatment of the insane person for a considerable time, for of all ailments insanity was one which was costly to nurse and required time for its treatment and recovery. The formation of a correct prognosis required experience, skill, and insight into the nature of the disease, as well as knowledge of its cause and origin. The peculiar constitution of the patient, the general powers of recuperation, the soundness or tainted neurotic quality of his parentage, the actual form or kind of insanity he had developed, and the circumstances in which that development had been reached—all these were points for careful thought and judgment. The age and sex of the patient, the epoch of life—puberty, adolescence, pregnancy and the puerperium, the menopause and old age—all had to be considered in prognosis. External influences also modified the disease and in this category were included access to pure air and sunshine, abundant supply of good nourishment and facilities of nursing, there being for the individual as well as for organised society a law of relation of mental health to environment. Insanity in whatever form it affected the individual shortened life; the average rate of mortality of the insane population of Great Britain was six to seven times that of the sane general population. In European and American asylums the official statistics bore out the same conclusion as to the high death-rate of the insane. Thus the average annual death-rate in these asylums was 8 to 12 per cent. of the average number resident—a proportion more than six times that prevailing in the general population. Dr. Jones estimated that of 100 persons attacked with insanity 30 recovered and remained well, while the rest died or passed into chronic dementia or partially recovered to recur again and finally lapsed into dementia. Three out of ten patients who developed insanity therefore recovered and remained sane for the rest of their lives; seven died insane sooner or later. Complete recovery with full immunity against recurrence was rather rare and exceptional. They were thus justified in looking upon insanity as a diseased state which shortened life and upon the insane as a class which was marked by considerable physical inferiority and lowered vital resistance to disease. The special proclivity of the insane to pulmonary tuberculosis also rendered prognosis grave in both the congenital and "acquired" insanities. A higher percentage of girls than boys recovered from the insanities and minor psychical disturbances of adolescence, the period of 18 to 25 years of age. Most cases of insanity did not come under treatment during the early manifestations of mental disorder. There were other factors, such as the long-continued action of determining causes, as alcoholism, plumbism, dissolute living, years of misery and destitution, which also entered into the question of prognosis. In young children the occurrence of insanity was of very bad prognosis and the presence of syphilis or epilepsy rendered the prognosis worse. General paralysis and acute delirious mania were of fatal prognosis, the mortality reaching to nearly 100 per cent. Among the insanities proceeding from congenital or embryonic anomalies of brain development were paranoia, folie raisonnante, the insanity of cranks and eccentrics, and epileptic insanity of the young which were found to be incurable. Neologisms—the habit of inventing words and phrases of mystic meaning—and verbigeration were of bad prognosis. A good environment, concluded Dr. Jones, was potent for healthy development in cases where hereditary taint was not overwhelmingly bad and he thought that every effort should be made by parents and teachers to bring up the infant and young child in a morally and physically healthy environment.

In the discussion which followed

Dr. A. R. URQUHART (Perth), the President of the section, expressed his general concurrence with the views of Dr. Jones as enunciated in his paper which was full of scientific and practical interest.

Dr. T. B. HYSLOP (London) said that in senile insanity the prognosis depended more on the condition of the patient's arteries than upon the mere age. His experience with regard to adolescents was that the "exhaustion psychoses" were coming more into prominence of late years. He considered that the study of the charts of insomnia was a valuable aid to prognosis and that in some cases a fairly definite prognosis was possible to be formed as to curability.

Dr. W. LLOYD ANDRIEZEN (London) argued that death-rates in asylums should be calculated on the yearly census—i.e., the average number of patients resident per annum—and not on so inconstant and fluctuating a quantity as the yearly admissions. He agreed with the estimate that 70 per cent. of recoveries might follow early admission and treatment but thought that many recurred later. Paranoia and the degenerative psychoses were incurable, because the underlying anomalies of cerebral development began in pre-embryonic life and continued after birth. He concluded by stating that the prognosis in insanity was worse than Dr. Jones's estimate of it, as his own investigations brought him to the conclusion that out of 11 persons who developed insanity nine ultimately died insane and that of the remaining two but one recovered perfectly.

Dr. D. BOWER (Bedford) said he concurred in the view that insanity shortened life but did not believe that tuberculosis was more frequent in asylums than amongst the general public. Where hereditary tendency to insanity existed patients became insane from slight causes but they readily recovered. Such recoveries were, however, followed by frequent recurrence under new stresses.

Dr. L. R. OSWALD (Glasgow) said that to forecast the date or time of recovery was very difficult. He believed that acute mania was more often recovered from than was melancholia proper and that in senile cases a healthy condition of the arteries was of favourable significance.

Dr. T. JOHNSTONE (Leeds) regarded tubercle as the result of "a weakening of the peripheral nerves," and gave instances illustrating this view from influenza and its sequential broncho-pneumonia and cardiac failure. Cases of general paralysis followed mild syphilis. Prognosis in senile insanity might be good *quâ* insanity but was bad as regards life.

Dr. FLETCHER BEACH (London) agreed that the earlier the age of onset of insanity the worse the prognosis, especially when insanity appeared in early childhood. Congenital imbeciles were, he thought, capable of manual training and of increase in intelligence, as was proved by the experience of the special centres for their education under the London County Council. Epilepsy shortened life only when the epileptic was insane but he did not think it was true with regard to sane epileptics such as formed the "colony" at Chalfont St. Peter. The conditions there were favourable to lengthen rather than to shorten life.

Dr. JONES then briefly replied to the comments made, and questions raised, on his paper.

Dr. L. D. H. BAUGH (Glasgow Asylum) read a paper on

Confusional Insanity.

He believed that in many cases they were due to the toxæmias of sepsis, acute specific fevers, alcohol, and the puerperium. The material used was collected from 47 cases which had been under his care and observation during the past three years at the Glasgow Asylum. The cases showed a fairly definite group of symptoms, psychical and physical. The mental symptoms were a purposeless resistiveness, confusion, absence of emotion, and a facial expression like "embarrassment." The physical symptoms were cutaneous disturbances of circulation, leucocytosis, the presence of indoxyl in the urine, and the special symptoms proper to the physical ailment. Dr. Baugh then proceeded to deal with these symptoms *seriatim*. Purposeless resistiveness, he said, was found in all the 47 cases; emotion was absent in 32 cases, and in the remaining 15 it was only occasionally present and that merely for short periods. These figures regarding the condition of emotion showed a great difference from those of ordinary mania and melancholia in which an emotional state was always a dominant factor. Embarrassment and the fixed facial expression were present in all the 47 cases. The presence of indoxyl in the urine was tested for only in the last 19 cases and found to be present in excess in all. Leucocytosis to the extent of over 9000 per cubic millimetre of blood occurred in 24 out of 33 cases which were examined. Over one-sixth of the total cases were considered to be the result of a toxin acting directly on an unstable nervous system, and in these a preliminary mental confusion led to a febrile or post-febrile delirium; symptoms of auto-intoxication, judged by indoxyl, were not present until after delirium. The probable proportion of cases due to toxæmia was reckoned to be more than one-sixth of the total number. In all the cases there was a definite causal relationship between the physical and the mental phenomena, the constant symptoms being a persistent vaso-motor condition, leucocytosis and indoxyl in the urine, mental confusion and absence of emotion, a fixed facial expression, and purposeless resistiveness, which completed the picture of what he would call a definite clinico-psychological type of insanity.

The PRESIDENT congratulated Dr. Baugh on the excellence of the paper and the practical insight that it displayed in dealing with an obscure form of insanity. The proceedings then terminated.

TROPICAL MEDICINE.

FRIDAY, JULY 28TH.

Mr. JAMES CANTLIE (London) opened a discussion on

Sprue.

He stated that up to the present no micro-organisms had been proved to be causative of sprue, although organisms had been described in connexion with the investigations of the disease. Apart from the question of micro-organisms sprue was a disease of persons who had resided for a considerable time in certain tropical countries, more especially the Malay Peninsula and Archipelago, Indo-China, Southern China, Southern India, and Ceylon, but typical cases of the disease occurred in mid-China, Japan, and possibly other countries to the north of the equator. Atony or physiological atrophy of the liver was an early, perhaps the earliest, condition in all cases of sprue and the stomachic and oral troubles usually preceded the intestinal flux characteristic of the disease. Persons who had dwelt for some years in an area where sprue prevailed were liable to a form of stomatitis accompanied by tender tongue and ulcerative patches on the inside of the lips and cheek and on the gums, tongue, and palate. Repeated attacks of this condition of the mouth were prevalent, as many as three or four or more occurring during 12 months; attacks lasted about three weeks and these in time might or might not be followed by the intestinal flux typical of sprue. When established there was no possibility of confusing sprue with any other of the intestinal lesions; the tenderness of the mouth, the bulky frothy pale morning stools, the loss of weight and the anæmic condition of the patient formed collectively a group of signs and symptoms indicative of the nature of the ailment. The treatment consisted in bringing about the physiological activity of the liver. This could not be done by milk and Mr. Cantlie stated that at the second meeting of the Section of Tropical Medicine in 1898 he had declared against the treatment of sprue by milk and subsequent experience had still further confirmed him in his view. A milk diet (milk and nothing else) would certainly in time check the diarrhœa and so would certain medicines, but this did not cure the disease. The fæces of a patient suffering from sprue and taking milk were not in any sense fæcal, the motions neither smelt nor looked like fæces and consisted of the almost pure curd of the milk passing quite undigested. The patient lived on the whey extracted from the milk and rejected the curd in a cheesy mass—the so-called solid stool of the patient suffering from sprue when on milk. By a milk diet the liver did not increase in size and no true bile appeared in the stools On giving meat—a wholly meat diet—the stools immediately showed the presence of bile, the liver increased in size rapidly, and the aversion to food disappeared. When the patient was very weak and a fatal issue threatened fresh meat juice, raw or lightly cooked, might have to be given every five or ten minutes for a day or two, but afterwards the interval of feeding grew gradually longer until two or three hours might intervene. After a day or two beef jelly, beef tea, calves' foot jelly, scraped beef, pounded beef, and minced beef might be added as the patient's condition improved. For a patient taking meat five ounces of pounded beef were given morning, noon, and evening, with jelly between each meal, and freshly made weak tea, rice tea (rice put into the oven, roasted brown, and infused in boiling water), and rice water (water in which rice had been boiled) for drink. The good done by meat was partly no doubt due to its freshness, as sprue was seemingly allied in its nature to scurvy and the fresh juices of all meat or fruits were beneficial. In this manner could be explained the beneficial action of strawberries and other fruits. Medicines beyond an occasional dose of castor oil were uncalled for, although Dr. Begg found great benefit from santonin. He (Mr. Cantlie) had also found santonin useful. Cases of sprue arose in England many years (even seven or eight) after the patient had returned from the tropics.

Lieutenant-Colonel **ANDREW DUNCAN**, I.M.S. (London), read a paper on

Hill Diarrhœa.

The disease appeared most frequently amongst persons in India leaving the hot plains for change in the hills. Colonel A. Crombie held that hill diarrhœa was due to the presence in the digestive tract of some organism which multiplied there, devoured the colouring matter of the bile and perhaps other constituents, and so allowed of rapid fermentative changes in the intestine. Lieutenant-Colonel Dyson, I.M.S., considered that hill diarrhœa occurred in those hill resorts where the geological formation contained schist; in hill stations resting on sandstone the disease did not occur. The mica from the schist caused irritation of the alimentary canal, fermentative changes supervened, and a micro-organism developed, causing diarrhœa. In hill diarrhœa there were no oral symptoms nor was there any diminution of liver dulness as in sprue. The treatment advised by Colonel Crombie was in mild cases from 12 to 15 grains of pepsin. Ingluvin or lactopeptin was given two hours after food which must consist of milk. In severe cases five ounces of peptonised milk were given every two hours day and night and drachm doses of liquor hydrargyri perchloridi 15 minutes after a meal. This treatment, combined with rest in bed, would prove successful in a few days.

Dr. L. W. **SAMBON** (London) considered that sprue was undoubtedly due to a micro-organism and that the long incubation period which at times precedes the manifestation of sprue was by no means unique.

Dr. **DAVID J. GALLOWAY** (Singapore) also considered that sprue was due to a micro organism. He had no doubt of the infectious nature of sprue and cited numerous instances of the wife infecting the husband and *vice versâ* and similarly other members of the family. He objected to the term "sore tongue," as the tongue might be seriously affected without pain. The whiteness of the stools was likely due to the type of fermentation which took place in the intestine. Anæmia was a very pronounced symptom of sprue. He considered that drugs played a useful part in the treatment of sprue and he believed that intestinal asepsis was highly beneficial. Milk treatment had in his hands given most satisfactory results.

Dr. **ALBERT J. CHALMERS** (Ceylon) thought that sprue was rarer in Ceylon than it used to be. The treatment he had found most useful was "liver soup" (an old treatment in Ceylon) combined with intestinal disinfectants.

Dr. J. **CAMPBELL GRAHAM** (Sumatra) stated that sprue was not common in Deli, Sumatra. Europeans were proportionately more often attacked than were the Javanese, but as most stomachic derangements were termed sprue in Sumatra and Java there was much confusion between real sprue and other troubles. He gave a summary of Dr. A. van der Scheer's paper on Indian Sprue which he had translated and condensed. This authority considered that the signs and symptoms of sprue were due to abnormal digestive processes going on in the bowel which were indicative of an enterogenous auto-infection; he also, as stated by Mr. Cantlie, considered suppressed appendicitis a potent agency in the causation of sprue and proposed removal of the appendix as a means of cutting short the ailment.

Dr. F. O. **STEDMAN** (Hong-Kong) believed in the benefits of the milk treatment in many cases of sprue with an intestinal antiseptic such as beta-naphthol. A form of diarrhœa which occurred in Hong-Kong after the first heavy rain was probably due to micaceous particles in the water which was slightly opalescent at that period of the year.

Dr. C. F. **HARFORD** (London) alluded to the seriousness of diarrhœa from whatever cause in the tropics and advised that more serious attention should be given to the subject of early intestinal flux. Intestinal derangements were the cause of a large number of persons being invalided in hot countries and our present knowledge of the pathology, prophylaxis, and treatment of these ailments was largely of an empirical nature. He would advise the schools of tropical medicine to give more attention to the diseases of the alimentary canal than had been hitherto done.

Mr. J. H. **EBELL** (Colombo, Ceylon) referred to the liver soup treatment of intestinal flux in Ceylon and to the use of toddy, the fermented juice of cocoanut palm, as an effective means of treating sprue.

Dr. **JOHN HUTSON** (Barbados) stated that what was regarded as thrush in Barbados was really sprue. Pellagra often complicated the disease in Barbados. A strict banana diet, he had found, cured cases of sprue in from three to four weeks and small doses ($\frac{1}{100}$th of a grain) of corrosive sublimate frequently repeated seemed to be beneficial.

Major G H. **FINK**, I.M.S., said that in his experience in India the sterilised milk treatment was successful. He was inclined to agree with the idea that mica in the drinking water played a part in the causation of hill diarrhœa. He advocated more extensive investigation of native drugs and remedies.

Dr. W. L. **STRAIN** (Brazil) stated that he could not remember during a 20 years' experience ever having seen a case of sprue in Brazil, although intestinal troubles were rife. When diarrhœa took the fermentative form with pale, foul-smelling stools the use of some form of ox bile had proved highly beneficial and a pill containing ox bile made by Erba of Milan was largely used in S. Paulo for most forms of diarrhœa.

Lieutenant Colonel **DUNCAN** stated that he believed that milk could cure sprue but the treatment recommended by Mr. Cantlie was more speedy and developed the liver in a way which milk never could.

Major **FINK** contributed a paper entitled

The Mosquito Malarial Theory and Malarial Prophylaxis from the Latent Phase.

This paper, already published in pamphlet form, dealt with the constant source of malarial fever in tropical countries as opposed to the accidental. Major Fink did not consider that the constant source of malarial fever lay in the mosquito, while even as an accidental cause it occurred in perhaps from 5 to 10 per cent. of the cases by the mere bite and nothing else.

Dr. H. HEARSEY, principal medical officer, British Central Africa, contributed a paper on

Malarial Fever in British Central Africa.

He stated that in British Central Africa the forms of malarial infection were the tertian and the æstivo-autumnal. The tertian type was the commoner and was of either the single or double tertian variety. The tertian forms were amenable to quinine, whereas the "multiple" infection forms and æstivo-autumnal fever were generally resistant to quinine. Dr. Hearsey was inclined to regard hæmoglobinuric fever as a pernicious form of the æstivo-autumnal variety and was inclined to attribute the disease to (1) anæmia due to long-standing malaria, rendering the hæmoglobin more unstable and permitting of its liberation on slight provocation; (2) a sluggish condition of the liver; and (3) the presence of nephritis. In the treatment of hæmoglobinuric fever quinine must not be given. A mixture of bicarbonate of sodium (ten grains) and perchloride of mercury (30 minims) every two or three hours served to prevent suppression of urine; an injection of half a grain of morphine helped to control vomiting; nourishment was maintained by the ordinary invalid food and drink, and brandy was used to the exclusion of other stimulants.

Dr. ST. GEORGE GRAY (Sierra Leone) sent a paper entitled

Notes on the Method of taking Quinine in the Prophylaxis of Malaria.

He was of opinion that a person who took five grains of quinine daily was pretty sure to escape malarial fever; those taking three grains daily, however, were more frequently attacked. These quantities in time, however, were liable to cause deleterious consequences. Dr. Gray suggested that as the life cycle of the parasite was about 48 hours in Sierra Leone and that fever developed eight or ten days after infection a full dose (10 or 15 grains) of quinine should be taken on two successive days with an interval of eight or nine days before the next two doses were taken; by this plan the parasites would always be destroyed before they could cause fever, and it presented several advantages over the daily or alternate day's dose of quinine.

Mr. CANTLIE contributed a paper on

Recent Cases of Abscess of the Liver.

He reported two cases of abscess, one in a patient from Brazil and the other in a patient from India; in both cases the pus was on the upper part of the liver; both were cured in about three weeks by the large trocar and cannula and syphon drainage plan of treatment. In two other cases, both from India, the pus had infiltrated and destroyed the whole of the lower lobe of the right lung; both patients died in spite of free drainage by removal of ribs and packing the pleural cavity with gauze. Mr. Cantlie also gave notes of a case of abscess of the liver in which gangrene of the right half of the liver resulted in all probability from an infective embolus in the right branch of the portal vein. A sixth case referred to was that of an abscess in the liver in a man who had never been out of England. The pus in this case showed the abscess to be due to streptococcal infection; the patient, after the abscess was tapped and drained, had a prolonged period of high evening temperatures, but ultimate recovery now seemed probable.

Dr. ALDO CASTELLANI (Colombo, Ceylon) sent a paper on

Diarrhœa from Flagellates.

In cases of diarrhœa which came under Dr. Castellani's notice in Ceylon he found flagellates in the evacuations. Methylene blue was very poisonous to blood flagellates (trypanosomes) and a solution of this drug proved to be equally so to intestinal flagellates in laboratory experiments when injected per rectum. The flagellates present in the fæces could be divided into three groups:—(1) large, pear-shaped bodies, from 18 to 25μ in diameter, possessing an undulating membrane, two or three flagella at one pole and a short flagellum at the opposite pole, with indistinct nucleus and several apparently non-pulsating vacuoles; (2) small roundish bodies from 8 to 12μ in diameter, no undulating membrane, with one flagellum only but no vacuoles (these were probably cercomonata); and (3) roundish non-motile bodies from 15 to 20μ in diameter, staining blue by Romanowsky's method, with sometimes a few vacuoles. Associated with these flagella in one case were found the protozoal parasite, lamblia intestinalis, and a protozoon which provisionally Dr. Castellani termed entamœba undulans. Infection of laboratory animals gave negative results. Several observers had described cases of diarrhœa due probably to flagellates, but hitherto the tendency had been to believe that the parasites were harmless; from the fact, however, that diarrhœa occurred when the flagella were numerous and disappeared when the flagella were in minute numbers a certain probability as to cause and effect would seem to be indicated.

Mr. J. TERTIUS CLARKE (Perak) read a paper on

The Present Theories of the Cause of Beri-beri.

He dealt with the subject under the following heads: (1) The arsenical theory of Ross; (2) the "rice" theory; (3) the "place" theory; and (4) the acute or subacute infectious disease of Dr. Hamilton Wright. Mr. Clarke tried to infect monkeys by causing bugs from the beds of patients suffering from beri-beri to bite monkeys but the results were negative. Moreover, ward attendants did not contract beri-beri as a rule. He related one instance where a Chinaman acted as ward attendant in beri-beri wards for nine years and never contracted the disease, yet when he went to do tin-mining he went back to hospital in a few months with beri-beri. Still it was a fact that the disease might infect a "place," might disappear from that "place," and disinfection might apparently prevent further cases. No Tamils acquired the disease though the rice supplied to them was actually the same and cooked in the same vessel with the rice supplied to Chinese. It might be worthy of note, however, that the Tamils always took a quantity of pungent curries and essential oils with their meals whereas the Chinese seldom did.

Dr. HAMILTON WRIGHT (formerly of the Federated Malay States) believed that beri-beri was due to a specific organism which gained entrance to the body *viâ* the mouth, that it developed and produced a toxin chiefly in the pyloric end of the stomach and duodenum, and that the toxin being absorbed acted atrophically on the peripheral terminations of the afferent and efferent neurons. Further, that the specific organism escaped in the fæces and lodged in confined places through accident or the personal habits of those affected by the disorder, and that in the presence of congenial meteorological, climatic, and artificial conditions of close association from overcrowding, the organism became virulent and gaining entrance to the healthy body in food, &c., contaminated by it gave rise to an attack of the disease. The fact that the germ remained so closely local could, he thought, be explained by its being at once destroyed by the action of direct sunlight or that the presence of carbon dioxide or some other gas was necessary for its virile development. It seemed from his observations that the active stage of the organism in the body was between three and four weeks. He based this estimation on the facts that the preliminary feeling of oppression in the epigastrium ceased at the end of about three weeks and that it was rare to find the lesion of the gastric and intestinal mucosa in cases of only six weeks' standing.

Dr. R. T. HEWLETT (London) contributed a

Note on Two Cases of Beri-beri Paresis treated with Injections of Strychnine.

After a course of strychnine, iron, and arsenic combined with galvanism little or no progress in the amelioration of the paresis was noticeable but when one-fiftieth of a grain of strychnine was administered subcutaneously twice daily a rapid improvement was observed in a week's time.

Dr. STEDMAN gave details of an outbreak of beri-beri which occurred on board a sailing ship ten days out from New York in which the contagious nature of the disease seemed to be pronounced.

Dr. STRAIN had seen sporadic cases of beri-beri occurring in women after childbirth in Brazil.

The PRESIDENT of the section (Professor R. W. BOYCE), Major FINK, Dr. GALLOWAY, Lt.-Colonel DUNCAN, and Mr. CANTLIE also joined in the discussion.

MOTOR AMBULANCES. — The Metropolitan Asylums Board, at its meeting on August 5th, accepted the tender by Messrs. James and Browne, Limited, of 395, Oxford-street, London, W., to supply a chassis suitable for an ambulance carriage.

THE LANCET.

LONDON: SATURDAY, AUGUST 19, 1905.

Lord Roberts on Imperial Defence.

It is not easy to exaggerate the gravity of the position about which Lord Roberts warned the London Chamber of Commerce at a special meeting held at the Mansion House on August 1st. The great general declared that this nation, in point of readiness and efficiency, is at the present time altogether unprepared for war in support of our Imperial interests against any great military power and that our position not only has not improved since the time of the South African campaign but has, indeed, become worse. The successful issue of that war was, he added, in no small degree attributable to the relative inferiority of our enemy in numbers, discipline, and organisation, so that the same results might not have occurred had we been fighting against one of the armies of a European power. Looking back on all that took place during that anxious period and considering that during the South African war this country was left absolutely denuded of all regular troops we realise in what a humiliating and even dangerous situation we were then placed. We have no desire to dwell on the dark days of our South African defeats or on the various commissions of inquiry with their saddening outcomes. So far as these investigations disclosed the medical and sanitary shortcomings of the campaign, with their real or alleged causes, they were fully discussed by us at the time, so that we may assume that our readers are acquainted with their significance. But Lord Roberts's message to the country can only be estimated at its full value by those who can recall to their minds the history of the South African war. And surely no one who has his country at heart can have forgotten it.

Lord Roberts, holding the views that he does on the need for the improvement of our Imperial defence, considered it his proper course in the first instance to give expression to them in the House of Lords. This he did, it will be remembered, recently, but it was, as he said at the Mansion House, to the country generally that he desired to appeal. It was indeed time that someone in authority should strive to rouse the nation from the state of lethargy into which it has fallen and this has now been done in a bold and comprehensive spirit both in regard to the strictly combatant and the medical branches of the service. Lord Roberts, who has been a man of war from his youth up, fully realises that we cannot always rely upon a pure policy of diplomacy and conciliation for procuring us peace. "When a strong man armed keepeth his palace his goods are in peace"; in other words, peace can only be made sure by readiness for war. This security, Lord Roberts declares, can only be obtained for our country by introducing some form of universal training and service for home defence. By the provision of such a system, in the course of time Lord Roberts believes that such a state of readiness and efficiency would be reached as would put it outside the interests of any foreign power to risk war with us, while we could meanwhile avoid the rigid system of army conscription adopted by our more strictly militant rivals. All the points raised and discussed by Lord Roberts in the course of his long speech are based upon the need in this country of organised preparation for war, and we may say at once that it not only seems to us right that there should be some system of obligatory military training on the part of the youth and young manhood of this country but from a medical standpoint we hold that it would prove highly beneficial. The effect of a military training, even of the most modified sort, is to strengthen the character and manliness of a people; health and physical vigour improve, while discipline tends to develop the intelligence, to increase alertness of thought and action, and to inculcate a habit of prompt obedience—all of which are undeniably good, valuable, and useful qualities. We have recently had some illustrations of the military material ready to hand and available at our public schools. Instruction in drill and the use of a rifle no boy dislikes, while camp life is keenly relished by every lad of ordinary spirit and he is physically and morally the better for a spell of it. The hatred of so-called "militarism" in this country is too easily turned into an excuse for shirking patriotic duty. We are not advocating Napoleonic conscription or, indeed, conscription at all as it is understood in France or in Germany. Such conscription may be our lot, though the drawbacks to it are undoubted. But for the present so extreme a course is not in question. But the youth of our nation want to be instructed in military discipline and the rudiments of military life, and every effort on the part of our military and educational authorities to arrive at this result will have the hearty support of the medical profession.

We hope that what Lord Roberts has to say about the Army Medical Service will be carefully read and studied by all. It will be seen that the late Commander-in-chief describes the exceptionally difficult and adverse conditions with which the medical officers had to deal and that he vindicates them from all blame in connexion with the lamentable occurrences and deficiences which were brought to light in the course of the South African campaign. But have we been taught by the sad experiences which we gained there and by the object lesson which we have had elsewhere? Are we better prepared for sending large forces into the field satisfactorily equipped for the prevention of disease? Lord Roberts, it will be seen, says that we are not much better off at present as regards our medical requirements than we were in 1899. In that case, whatever may have been the proposals of the Advisory Board, we have still to see the effect of them. The present unsatisfactory and chaotic state of military affairs demands a statesman who can take a grip of the whole subject. The means and the material at the disposal of the British empire are the envy of other countries, so that it ought to be possible to organise a scheme of Imperial defence and medical aid in war in which this country and her colonies could take a coöperative share and responsibility.

School Legislation and the Demands of Hygiene.

IT is certain that none of those responsible for the introduction of compulsory education into this country foresaw all the developments which would ensue as necessary adjuncts of this system. If we force all children to attend school we are compelled to take all possible steps to secure that they shall be exposed to no avoidable risk in so doing. Hence arises the need not only for careful inspection of school buildings to see that they conform to the requirements of modern sanitary science but also for examination of the children themselves to insure that they are in a fit state of health to profit by the teaching provided for them and to guard against the introduction of infectious diseases into the schools. The risk of the spread of such maladies among children who are crowded together for purposes of instruction has often been pointed out and is, no doubt, real enough; yet it is not impossible that an undue burden of blame has been laid upon school life as the main factor in the spread of epidemics. Such, at least, is suggested by the results of an important research carried out by Dr. MYER COPLANS and embodied in a report made by him to the Gloucestershire education committee, a report to which we have previously made reference in these columns. In the area to which the report refers a very large proportion of the infectious diseases special to children occurred in those who were not yet of school age, being spread by home conditions, and Dr. COPLANS points out that only a comparatively short period of time is actually spent at school, amounting to about 51 full working days, or one-seventh of the whole year—"the remaining six-sevenths are passed beyond the ken or control of the education authority." Opportunities for infection at home and in the course of play are plentiful and must not be overlooked. Indeed, it is even doubtful policy in Dr. COPLANS's opinion to close schools in the presence of an epidemic, since such a measure results in increased association among the children elsewhere without the supervision which is possible at school. We must, on the other hand, remember that the conditions within a closed building such as a school, with only moderate ventilation and with close personal contact, are more favourable for the transmission of contagion than those prevailing during outdoor play, so that it is difficult to acquit school life of the responsibility for much of the infective disease arising among children. If this is true of the zymotic maladies it is even more certainly the case with such grosser forms of parasitic disease as pediculosis. The complaint of parents who strive to keep their children clean and respectable is always that association with infected individuals at school is so constant that their best endeavours are futile. The prevalence of this evil is sufficiently proved by the figures supplied by Dr. COPLANS. Out of 6652 children examined no less than 908 were unmistakably suffering from the presence of vermin or their eggs; and as it is easy to overlook a few nits in a thick head of hair it is probable that these figures are rather short of the actual truth. The proper course to be adopted for eradicating this evil is not quite clear in the present state of the law. A child can, indeed, be excluded from school on account of the existence in him of infectious disease, but there is unfortunately no very satisfactory means of insisting upon the parents taking adequate steps towards cure at home. Continued failure to apply the remedies needed might, perhaps, constitute "neglect" of the child in the eyes of the law, and we have heard of instances in which the Royal Society for the Prevention of Cruelty to Children has brought pressure to bear upon refractory parents with satisfactory results, but some more reasonable machinery than this is required. If teachers notice cases of the disease at school something may be done to prevent its spread to others by making such children sit at separate desks; and for this purpose it is necessary to provide a certain number of desks fitted for the use of only one scholar at a time; indeed, the ideal state of affairs would be the provision of such a desk for each child in the school. It is needful further to bear in mind that the cloakroom may be a source of infection as well as the classroom, and to exercise some supervision over the garments as well as over the persons of sufferers from this complaint.

A second point of much interest, which is brought out in Dr. COPLANS's report, is the unsuitability of the clothing of many children in our schools. Among the children whom he examined this was most notable in the cases of the infants and of the girls, the former being swathed in a multitude of garments, sometimes as many as eight layers thick, which must necessarily be hot and cumbersome and interfere with the free movements of the limbs; while the girls were victimised, like their elders of the same sex, by the use of corsets. These were often the cast-off appliances of their mothers or elder sisters and were seldom well-fitted to the actual wearers. The girls suffered also from the clumsy construction of their outer dresses, for it was found in many cases that they were unable to stretch their arms above their heads without tearing their frocks. This may seem a small matter but in view of the importance now rightly attached to physical exercises and drill such ill-adapted clothing is seen to be a serious impediment to proper development. Nor is the remedy easy to devise, since it is not part of the duty of the educational authority to instruct the parents of the children in hygienic dressmaking. Probably the evil will work its own cure and the trouble involved in mending the rents produced by school drill will impress on the mothers of the girls the need of supplying them with more suitable costumes. The boys examined by Dr. COPLANS were apparently better off in respect to their attire but were cumbered with boots of excessive weight. Perhaps part of the clumsy gait noticeable among the youths of our lower classes may be traced to this peculiarity of foot-gear during their boyhood. Slight defects in the sight and hearing of children are now recognised as accounting for some cases of apparent mental backwardness and on these points many recent observers have written in our columns and elsewhere Whether it is the case that ocular defects are more common than they used to be or whether it is only that their existence is recognised and treated now, whereas formerly they passed unnoticed, certain it is that errors of refraction are very commonly found when looked for among children at school and that correction of these errors has often a most beneficial effect upon the health of the little patients. One of the most important duties of the medical inspector of a school consists in the detection of such cases. Still more conspicuously associated with signs of mental defect is the existence of deafness, and children who are found to be backward at school, while they are reported by their parents to be bright and intelligent at home, may often be found to suffer from this malady. At home familiarity with what is probably required from them takes the place of accurate hearing, while at school the inability of comprehension passes for inattention or stupidity. The frequency of aural discharges among the children of the poor is only too striking to anyone who has worked in the out-patient department of a children's hospital, and in many cases the condition is lightly regarded by the parents and submitted to no treatment. It can hardly be doubted that many cases of deafness might be prevented by timely remedial measures and now that general attention has been drawn by many authorities to the importance of aural lesions, and to the train of serious consequences that may ensue from them in later life, it is to be hoped that teachers as well as medical officers will be on the alert to recognise the dangers and to insist upon proper medical care for the child.

The benefits of medical supervision are well brought out by a supplementary report made by Dr. COPLANS, in which it appears that an examination of children in the same schools for a second period of six months revealed an improvement in the number of infectious ailments of over 50 per cent., while the non-infectious maladies also showed a decline, though not quite to the same extent. With many other points of interest contained in the report in question, such as the proper lighting of schools, the type of desk advised, and the provision of paper and pencils instead of the old-fashioned slate, we have not space to deal here. We can only hope that the importance of the investigation here carried out will be recognised and that other education authorities will follow the good example of Gloucestershire in appointing efficient inspectors to the schools under their care and, in making their reports available for general information. In this way a valuable body of statistics will be compiled, and we may hope that the charge now levelled against our schools with only too much truth in a considerable number of instances—that they are responsible for more physical harm to some of the children than they confer mental benefit—will become a thing of the past. Our schools should instead become the means of diffusing a knowledge of the elementary laws of hygiene and should act as nurseries for a race of "good animals." For not the least materialistic among us can deny that it is "good animals" properly trained who become good citizens.

The Murri-Bonmartini Trial.

"INTELLECT, reinforced by culture," said an Italian statesman the other day, "is never lacking in Italy. What you miss is Character." This saying, of one who knew his compatriots well, has had striking illustration in the tragedy on which the curtain has just fallen in Turin—a tragedy in real life enacted in the "Mother City of Universities" by performers who, except the subordinates, were as intellectually and educationally developed as they were morally debased, and whose social activity, often as able as it was effective, stands in glaring contrast with the depravity of their *vie intime*. There is no need to recapitulate the sordid and sanguinary details. Judicial methods in Latin countries are so contrived that, long before the "juge d'instruction" has prepared his indictment, the minutest details of the *res judicanda* are public property—with the result that sides are taken in the interests of either party and that (as in the case now brought to a conclusion) it is impossible to impanel an unprejudiced jury in the locality where the incidents took place. Three years of judicial "preliminaries," three years of unwholesome curiosity fed by "information" more or less authentic, three years of suspense for the accused in prison and of abortive attempts to find and to fix the scene of trial, make the MURRI-BONMARTINI case only too typical of the administration of justice in the Italian kingdom. Justice, however, though moving *pede claudo*, as the poet puts it, has at length overtaken the guilty, and Bologna, the seat of a university and the centre of much that is most enlightened and progressive in Italy, has just seen two of her professional sons consigned to a living grave and two others of her citizens erased from the roll of society, as actors, primary or secondary, in a crime exceptionally horrible even in the Italian "Cronaca Nera." Signor TULLIO MURRI, the actual murderer of his brother-in-law, Count BONMARTINI, is an "avvocato" or barrister whose university record and professional ability marked him out for an honourable career; in fact, at an age unusually early he held a place in the communal council of Bologna. His sister, the Countess BONMARTINI, was the pride of her family for intellectual gifts and for accomplishments more than feminine and she, too, was active in Bolognese society as a promoter of good works. Her paramour, Dr. SECCHI, was a consultant of much acceptance in the city and the province; and Dr. NALDI, though a physician by profession, was possessed of talents, mainly literary, which, while weaning him away from his special calling, would still have made him noteworthy among his peers. That four such persons, moving in refined, academic, and social circles, should have, with more or less complicity, been the perpetrators of a crime supposed to be specially characteristic of the criminal class, constitutes the astounding element in the case and serves to explain the line of defence indicated and all too elaborately wrought out by the astutest of their counsel: "in fin dei conti, faremo i tutti e quattro pazzi" (the long and short of it is, we'll make them out, all four of them, to be mad). And so, in supplement to the orthodox examination and cross-examination of evidence in which Italian "avvocati" are past masters, for days—nay, weeks—the court re-echoed to the phraseology of LOMBROSO and his disciples, seeking to prove or to deny the presence in the accused of this or that "lesion," physical or mental, which makes a man a "criminaloid" as distinguished from a "criminal-né," or, in the absence of any such indication, at least a "dégéneré." Highly interesting, no doubt, was this conflict of experts but small was the impression that it made on the court—all the more that, as already said, the public, thanks to premature and non-official "information," had taken sides, advanced Liberals sympathising with the Socialist MURRIS and ardent Clericals with the devotedly Catholic BONMARTINIS—while a considerable party loudly maintained in the press that all this super-subtle "attenuation" of crime was an unfair resource of the rich client as contrasted with the poor and that justice would be discredited in the eyes of the majority if testimony only procurable by the well-to-do should come in abatement of evidence which would have made short work of the proletariat. The presiding judge, while treating the experts with the consideration due to their profession, summed up on the lines traditional in such cases and with an eye to the "salus populi," propounded a series of "quesiti" to the jury, inviting them to weigh and to respond to them as they would in common life and to give their verdict accordingly. This the jury did with a fidelity that to the leading Italian organs of opinion is quite "reassuring" in the interests of justice, and in due course came the sentence which (*teste* the same opinion) is none too severe. Meanwhile, the heart of all Italy has gone forth in sympathy with the distinguished pathologist, consultant, and teacher whose fate it has been, at the sunset of an honourable and most useful career, to see his children excluded from society and his family name polluted by so dark and indelible a stain. Touching is it to read of the many old pupils, either in practice or holding academic chairs, who sought out their revered master and did their best to comfort him in his affliction. For ourselves, we can but add how sincerely we sympathise with AUGUSTO MURRI who has been an able contributor to our columns and whose kindness to the representatives of British medicine on Italian soil will ever be gratefully remembered.

Annotations.

"Ne quid nimis."

THE PRESIDENTIAL ADDRESS AT THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

ON August 16th the President of the British Association for the Advancement of Science, Professor G. H. Darwin, F.R.S., delivered the first part of his presidential address at Cape Town. The second part of the address is to be delivered at Johannesburg on August 30th. By the courtesy of the authorities of the Association we were supplied with advance proofs of both portions of the address. We have thought it well, however, to wait until the delivery of the second portion and to publish both portions together rather than to publish them separately. The subject of the address is "Evolution" and the term "evolution" has enormously widened its scope since the days of Professor Darwin's illustrious father who first applied the principle as a working hypothesis to the history of organic life, for nowadays the theory of evolution is applied not only to organic life but to the very constitution of the universe itself; and Professor Darwin, who in the first portion of his lecture made a general survey of evolution in its various branches and laid down certain general principles which in his opinion were common to them all, went on to show how general laws found an application in recent speculations as to the constitution of matter. He reminded his hearers that of late years the atom had been shown to be no longer an atom—i.e., that it was not indivisible. He announced at the end of his address that in the next portion he would consider various theories of evolution in the heavens. We therefore propose to defer any comment upon this most interesting address until we have published both parts of it.

THE HEALTH OF THE POPE.

AN Italian correspondent, under date August 12th, writes: "Just before the Supreme Pontiff was about to solemnise the second anniversary of his promotion to the Holy See he had one of those recurrent attacks of gout which, if not serious in themselves, are sufficient to cause a flutter in the ecclesiastico-political dovecots. There were considerable swelling and pain in the left knee, Dr. Lapponi was called in, and, having with local and general treatment induced the welcome relief, he left his august patient to the seclusion of his private apartments, with strict injunctions to spare himself the transaction of all but the least harassing business. Punctually carried out, the physician's prescriptions within 48 hours enabled His Holiness to give more than one audience and the following day to receive a deputation of some 40 persons. The incident derives its importance from the resuscitation of the proposal that the Pope should drop the rôle of 'prisoner with doors locked on the inside,' and for salutary change of scene and air transfer his quarters from the 'Palace and the garden' of the Vatican to his summer residence at Castel Gandolfo which for 35 years has never known the tread of pontifical foot. It is an open secret that no one would welcome this new departure more cordially than Pius X. who, not much beyond the meridian of life and accustomed to exercise in the fresh air, often misses

> 'The sea-pulse of the still lagoon'

and the breath of the Julian Alps, particularly when the thermometer registers 40° C. (104° F.) in the shade! But in his case, as in that of Leo XIII. and of Pius IX., the traditional policy of the Curia interposes its veto and the Ultramontane party, through which the 'obolo di San Pietro' chiefly finds its way into the pontifical exchequer, insists on his sustaining the rôle of 'despoiled monarch,' under the threat that any departure from that pose would be followed by a suspension of the doles of the faithful. This *argumentum ad crumenam* is all the more effective as it is well known that the economies introduced by Pius X. in the administration of the Vatican have failed to bring about that *pareggio*, or equilibrium between income and outlay, which he has so fervently at heart. So it is to be feared that attacks of recurrent gout notwithstanding—attacks, moreover, intensifying year by year—the Pope must bow to *force majeure* and afford one more illustration of the remark that, if 'uneasy lies the head that wears a crown,' not less so lies the head that wears the tiara."

COATINGS OF RADIUM FOR THERAPEUTIC USE.

AT a meeting of the New York section of the Society of Chemical Industry[1] Mr. Hugo Lieber described methods of preparing radium coatings for therapeutic use. The proportions of the radiations given off by radium and its disintegrated emanations are about 95 per cent. of α rays and about 5 per cent. of combined β and γ rays. Owing to their nearly negative penetrating power the α rays as well as the emanations are practically unavailable for therapeutic purposes when the radium is inclosed in glass tubes or similar containers. Even the superficial layers of a given preparation of radium are relatively impervious to the emanations and the α rays proceeding from the underlying layers. In order to obtain the full radio-active effect of a given quantity of radium it is essential, therefore, that the radium should be spread out in as thin a layer as possible in the form of a "radium coating" and that the α rays and emanations should not be intercepted by a glass vessel or other form of container. In preparing the coatings the radium is dissolved in a suitable volatile solvent and a suitable material is dipped in the solution. The material when dry remains covered with a thin film of radium. In coating celluloid rods, discs, or similar instruments with radium alcohol or amyl acetate forms a suitable solvent, as it temporarily softens the celluloid and enables the radium to be incorporated in the surface. The accidental removal of the radium is prevented by afterwards dipping the celluloid instruments in a solution of collodion which forms a thin tough protecting layer, permitting the α rays and emanations to penetrate freely. The radium solution (as well as the collodion solution) is dyed with an aniline colour in order to indicate which part of an instrument has been coated and to make evident the accidental removal of the radium coating. The advantage of using radium coatings prepared in this manner is readily shown by an electroscope. It is found that a delicate rod coated at its tip with radium bromide of 10,000 units activity and holding, therefore, very little radium compared very favourably in its effects with one gramme of the same salt contained in a glass tube or with ten milligrammes of radium bromide of 1,000,000 units activity in a very thin aluminium tube. The radium coatings make it possible to apply radium to practically any part of the body. Instruments so coated possess the great advantage that they can be sterilised without loss of radium, as the protective coating effectively resists even continued boiling.

OCCUPATION AND PHYSIOGNOMY.

THE medical man knows the value of studying the patient's face if he would diagnose thoroughly his patient's condition, and occupation, like disease, has an undoubted influence on the physiognomy. In ordinary conversation persons will be found sometimes amusing themselves by guessing at the probable occupation of a given person and an answer not far from the truth is very often forthcoming, based entirely upon the physiognomy of that person. There are, of course, certain conventionalities in regard to dress and toilet which materially help the diagnosis, but associated with the various occupations in life there is undoubtedly a type of face which more or less betrays the calling of its owner. Medical men, especially in hospital practice, find acquaintance with these types valuable. They may not be able, with the shrewdness of Sherlock Holmes or of his still acuter brother, to read a man's past, present, and future by a glance at him in the street, but they are able to gauge with considerable accuracy how far the history of the case, as given by the patient, is a truthful one, and how far it fits with his probable occupation in life. Calling must certainly have some influence over the physiognomy of the cabman, the omnibus driver, the butler, or the groom; each frequently possesses a type of face which wears so characteristic an expression as to make it not difficult to identify the vocation accompanying it. We speak also of the legal face, the scientific face, the ecclesiastical face, the musical face and artistic face, the dramatic face, and the military face. This is merely a broad classification but we disbelieve in the claims of the keen observer to an ability to differentiate to a finer degree. We have heard of hospital physicians who claimed to be able to say from a glance at the face that this or that man was a butcher, a grocer, a bank clerk, a lawyer's clerk, a commercial traveller, a stock-broker, a wine merchant, and so on. We think that the fame of these medical men as rough-and-ready detectives has been largely manufactured for them by enthusiastic clinical clerks; but that many medical men do possess great insight into the occupations of those who come before them is a truism. The question is often debated whether physiognomy is a growth of vocation or whether it shows that the vocation chosen is in accordance with the particular capacity and ability of the person to whom it belongs. In other words, if the barrister does not show the "legal face," the aspiring priest the "ecclesiastical face," the medical student the "physicianly face," the soldier the "military face," and so on, is that a sign that they have mistaken their calling? Is the man who "doesn't look a bit like a doctor" likely to fail because his physiognomic qualification is wanting? Or will he, whatever his original features, gradually come to acquire the type of the profession to which he belongs. The answer to the question is, of course, that both theories are right. A certain kind of face, the so-called scientific face, is so often seen among modern medical students as to prove that the owner of that cast of countenance is likely to adopt medicine as a career. Conversely, whatever the original cast of features a medical man may have possessed, the anxious, delicate, and absorbing work of medical practice will put a stamp upon them.

SIMPLE DIARRHŒA AS AN ABORTIVE FORM OF DYSENTERY.

AT the meeting of the Société Médicale des Hôpitaux of Paris on July 7th Professor C. Dopter called attention to the fact that simple diarrhœa may be an abortive form of dysentery. In an epidemic of dysentery manifest cases are always preceded by attacks of simple diarrhœa; then the epidemic becomes developed and side by side with cases of varying intensity are a certain number of cases of apparently simple diarrhœa; finally, the epidemic declines and the cases become less and less severe in proportion as they become less frequent and attacks of diarrhœa again appear. Patients suffering from this apparently simple diarrhœa may infect others and give rise to attacks of true dysentery. During an epidemic of dysentery it is impossible to establish dividing lines between cases of simple diarrhœa, mucous diarrhœa, muco-sanguineous diarrhœa, and sanguineous diarrhœa. Between the extremes are all possible intermediate forms. Jürgens has recently examined bacteriologically 25 cases of simple diarrhœa which occurred at the camp of Gruppe during an epidemic of dysentery. He failed to find the bacillus of dysentery in the fæces but in 21 of the cases the serum agglutinated this organism. Professor Dopter examined bacteriologically 11 cases of diarrhœa which occurred during an epidemic of dysentery. Seven of the cases were particularly mild; there was simple profuse diarrhœa (ten to 12 stools daily) accompanied by colic but without well-marked tenesmus and the symptoms rapidly declined in three or four days. In these seven the serum reaction was negative and in one the bacillus of dysentery was isolated. The remaining four cases did not yield to ordinary treatment and ran a prolonged course. But only symptoms of diarrhœa were observed; no trace of blood was found in the stools. There were from ten to 15 stools daily for 15 days in two of these cases, for 21 days in the third, and for 25 days in the fourth. In one case the bacillus of dysentery was isolated but in all the serum reaction was positive. Finally, serum treatment rapidly cured these patients in from two to five days. It is important to recognise the nature of such cases of diarrhœa, for no doubt it is by them that the disease is mainly transmitted. The same precautions should be taken with regard to them as in cases of manifest dysentery. When cases of diarrhœa occur during an epidemic of dysentery it is easy to take the necessary precautions but if they precede the epidemic or occur sporadically the difficulties of diagnosis are great. In slight attacks there is nothing to guide the physician but if the attacks are prolonged, and especially if severe and producing an algid state with thready pulse, suspicion of their dysenteric nature should be aroused. The finding of the bacillus of dysentery would settle the question but this is attended with great difficulties. It is easy to find the bacillus in manifest cases of dysentery but the process becomes difficult as the stools become fæcal-like. The serum reaction is useful within certain limits. In a case of true dysentery the serum reaction becomes positive about the seventh or eighth day. In cases of ephemeral diarrhœa, even of dysenteric nature, the reaction is negative. But if the diarrhœa lasts a fortnight or more the serum reaction will then be found positive. The test ought to be performed with the two recognised types of the bacillus of dysentery, Shiga's and Flexner's, for they present different agglutinability with the serum of the same patient. Even if the results are negative dysentery should not be considered as excluded. Cases of diarrhœa occurring during an epidemic of dysentery should always be treated with the same precautions as if they were manifest cases of dysentery. Isolated cases of diarrhœa, especially those which occur during summer, should be treated as suspicious. Thus may be extinguished oci of epidemics of dysentery which begin as attenuated forms of dysentery and lead up to manifest cases, becoming more and more severe in proportion as they become more numerous.

THE HOUSING OF DOMESTIC SERVANTS.

ALTHOUGH our domestic servants are in large part drawn from a class amongst which housing is very far from what it should be it would seem in keeping with the fitness of things that in the houses and flats of those who are in a position to pay relatively high rents the servants should be provided with rooms in which there are adequate cubic space, light, and ventilation. We are afraid, however, from certain preliminary observations which we have made that in at least a considerable number of instances the servants are housed under conditions which, did they exist in the dwellings of the poor, would be open to strong criticism, their safety from such criticism in houses of the rich lying in the fact that external appearances are sometimes a little deceptive. It is somewhat surprising to find some of the very worst accommodation as regards servants' quarters in quite modern flats, with a rental of from £150 to £250 a year and situated in the most fashionable parts of the metropolis. To us it is astonishing to find that those who have so far succeeded in life as to be able to pay these rents should be content to house their servants under conditions in which they can never enjoy direct sunlight and where even diffused light is but a matter of a few hours daily even in midsummer. In flats such as these there are good, even imposing, reception rooms and, perhaps, two well-lighted bedrooms. For the rest the rooms, being in a projection at the rear and separated only a very short distance from the projection of the adjoining flat, are almost in darkness and but very imperfectly ventilated. It is this condition of affairs, necessitating, as it does, the constant deprivation of sunlight and the almost perpetual substitution of artificial light, which tends to promote the pale-faced anæmic appearance sometimes seen in servants in the employment of the better-off class. It is difficult to understand how the well-educated classes, knowing, as they must, the enormous value, *quâ* health and the enjoyment of life, of light and fresh air, can allow themselves to take flats where they themselves are housed in comfort but where their servants live under conditions which, to say the least of them, must be eminently depressing. It would be well, in our view, if public opinion could be brought to bear so as to secure for servants proper accommodation in these flats in fashionable quarters. We should be glad to see this subject ventilated by the metropolitan medical officers of health in their annual reports and records furnished of the results of visits made to houses and flats with the object of ascertaining precisely how the domestic servants are housed.

METHODS OF SUPPRESSING THE ADULTERATION OF FOODS AND DRUGS IN THE UNITED STATES.

Mr. W. S. Glyn-Jones, barrister-at-law, in a communication to the Pharmaceutical Society,[1] referred to the adulteration of foods and drugs in the United States and the various standards of purity drawn up by the United States Board of Agriculture. These standards are based upon data representing materials produced under American conditions. It is of interest to note, for example, that white sugar must contain not less than 99·5 per cent. of sucrose and molasses not more than 25 per cent. of water. In Massachusetts the law may be enforced by prosecution. But more often a preliminary notification to an offending dealer, especially in the case of a first offence, to the effect that subsequent infraction of the law will be followed by prosecution, leads to the immediate withdrawal of adulterated foods from sale. A third method of enforcing the law is by publication. Under the laws of some States the only method of protecting the public lies in publishing in periodical reports lists of adulterated food with the brands and manufacturers' names and addresses. Sometimes lists of unadulterated brands are published as well. It is of interest to note that in Massachusetts it is illegal to give or to sell to a person under 18 years of age a cigarette, though the minimum age for snuff and tobacco is 16 years. It is illegal also to sell or to exchange any woven fabric or paper containing arsenic in any form. A detailed list of substances condemned as impure provides instructive reading. Thus, distilled water was rarely found pure, all samples examined being below the standard, in many cases containing higher residues than the tap water of the towns in which they were produced. The salutary effect of analytical supervision over foods and drugs is shown in a striking manner in the case of glycerine, only 5 per cent. of the samples examined in 1903 containing arsenic, as against 68·9 per cent. in 1899. This illustration serves also to show what can be done by persistent and systematic notification, since this result has been achieved with but a single prosecution in the courts. A most ingenious fraud was discovered in Brockton, Massachusetts. It was the custom of the proprietor of a store to keep all the whisky supplied to his patrons in the water tank of an unused water-closet. By an ingenious contrivance the ball-cock of the tank was so arranged that the inflow of water to the tank was usually cut off. When, however, a raid was expected the tank could, on a given signal to an attendant in charge, be emptied and flushed with water by pulling the chain, the whisky flowing down the sewer. There are various forms of adulterations which have been subdivided as follows by Mr. Lyman F. Kebler, chief chemist in the drug laboratory of the United States Department of Agriculture: (1) conventional adulterations to suit the tastes and demands of the public—e.g., bleached ginger and the artificial colouring of many products; (2) accidental or incidental adulterations arising from environment, carelessness, or incompetence; (3) arbitrary adulterations to comply with, or to take advantage of, certain fixed arbitrary standards; and (4) intentional adulterations for purposes of gain and competition. The last named is the most serious form of adulteration and is met with in many forms, a few of which are of interest:

---

[1] Pharmaceutical Journal, 1905, vol. lxxiv., p. 217.

borax, mixed with from 15 to 73 per cent. of sodium bicarbonate; phenacetin, mixed with acetic acid; potassium bromide substituted for potassium iodide; borax given for Rochelle salts; corn starch substituted for St. Vincent arrowroot; sound drugs mixed with inferior or exhausted drugs; honey mixed with cane sugar and glucose; pepper containing 60 per cent. of ground olive stones; beeswax mixed with 33 per cent. of cassava starch; turpentine, 25 per cent. of which in America is adulterated with kerosene; and cocoa labeled pure but containing corn and wheat starch and even powdered cocoa-shells. Many of these adulterations are not unknown in the United Kingdom. It is of interest to note the various laws of various States: thus, alum is prohibited in foods in Missouri; flour must be derived entirely from a single cereal (District of Columbia) and must contain from 9 to 18 per cent. of water, from 0·3 to 2 per cent. of ash, at least 10 per cent. of moist gluten and 5 per cent. of dry gluten (Porto Rico). Preservatives are forbidden in jellies (South Dakota), in sausages, butter-milk, and foods that can be otherwise preserved (Pennsylvania), and in dairy products (12 States). In some States the law requires the amount of preservative added to be stated on the label. Saccharin is prohibited in food (Washington). Tea must contain from 4 to 8 per cent of ash, of which at least 40 per cent. must be soluble in water, and at least 30 per cent. of aqueous extract (Porto Rico). Bread must not contain alum, sulphate of copper, borax, sulphate of zinc, or other poisonous or harmful ingredients, nor must it contain more than 31 per cent. of water or less than 6·25 of albuminoids (District of Columbia). The use is forbidden of hermetically sealed cans the surface of which in contact with the preserved food is coated with an alloy containing over 2 per cent. of lead (Pennsylvania). Some of the States prohibit the use of copperas for colouring vegetables, whilst others place a limit on the quantity of copper allowed and insist that its presence shall be stated on the label. In Porto Rico bread must not be transported in baskets or on horseback but must be sent in covered carts provided with doors. Pies and sweetmeats must be carried in covered cases lined with oil-cloth or glass and upon all stalls and in retail shops and restaurants eatables must be protected from flies by means of metallic covers. In conclusion, reference may be made to a stringent law in North Dakota forbidding the distribution of samples of drugs for advertising purposes. This law makes it a misdemeanour for any person to deposit upon the doorstep or premises owned or occupied by another or to deliver to any child under 14 years of age any patent or proprietary medicine, cosmetic, disinfectant, or antiseptic, or any drug or medicine that contains poison or any ingredient that is deleterious to health, as a sample or in any quantity whatever for the purpose of advertising.

EFFECTS OF UNCORRECTED ASTIGMATISM.

IN a pamphlet entitled "The Nervous Symptoms produced in Children by Uncorrected Refraction and Muscular Errors" Dr. J. H. Claiborne of New York dwells on the difference between European and American children as well as adults in their sensitiveness to slight defects of refraction. He maintains that even the working classes in America are more highly strung than those of Europe and that the children in their schools are built of more nervous and sensitive tissues and he attributes the difference to the terrific pressure under which life is maintained in America. The symptoms which he enumerates, and which have particularly come under his notice in practice, are chronic headache and, more rarely, that form known as hemicrania, blepharospasm, reflex phenomena presented by the stomach as nausea and vomiting, and squint. He has not met with cases of epilepsy, paralysis or paresis of the ocular muscles, or of chorea, but he thinks that uncorrected refraction may powerfully modify the mental and moral character of a child by rendering the acquisition of book learning difficult and painful. In another communication on the Axis of Astigmatism he states that the axis of astigmatism does not occur at haphazard. He has satisfied himself from his own observations on 1176 cases of astigmatism that in hyperopic astigmatism the arc of deviation from the normal is usually situated between the meridians of 45° and 135°, embracing therefore an arc of 90°. In myopic astigmatism the arc usually includes the axes of 135° and 165° or an arc of 30°, the zero of the scale starting on the right on both sides in the horizontal plane, as the frame is regarded from before. There is an arc of neutrality, which may be called the *right arc of neutrality*, of 30° lying between 15° and 45° on the one side of the circle and there is a left arc of neutrality which is between 135° and 165° on the other. The right arc of 30° lying between 15° and 45° has two axes of preference, 30° and 20°, and 30° occurs twice as often in hyperopia as in myopia, and myopia alone occurs at 20°. Within the left arc of neutrality, 135° to 165°, there is one axis of preference—viz., 150°, and this occurs with equal frequency in myopia and hyperopia. In 1176 cases of astigmatism 80 exceptional irregular cases were met with. Dr. Claiborne has devised a special form of Placido's disc, in which are drawn radiating lines in the preferred meridians in both hyperopic and myopic astigmatism with a convex lens behind a central aperture in the disc.

SUBJECTS FOR INVESTIGATION IN PHARMACOLOGY.

THERE is a certain analogy between the unwise speculator and the prescriber of new and little known drugs. The former transfers his investments from Consols which are practically safe to mining shares which may yield him a better return but are far more likely to swallow up his entire capital. The latter despises the wide range of drugs of vegetable, chemical, and animal origin which have been proved through a long course of years to have a definite value and prefers to rely upon new and comparatively untried drugs which may or may not yield him the desired results. It would, of course, be unwise to adopt an ultra-conservative position and to ignore new remedies altogether. New healing agents are most welcome when proved by clinical experience to possess advantages over older drugs. It is worthy of note that the older drugs still present problems which up to the present time have not been solved by the pharmacologist, the chemist, or the pharmacist. This fact is well shown in the Research List which has recently been issued to the press[1] by the British Pharmaceutical Conference. A similar list was commented on in THE LANCET[2] in 1902. In the list just issued many of the problems previously referred to are included as still unsolved. The active principles of many plants are unknown, including arnica, *Cimicifuga racemosa*, the bitter principle of the pericarp of bay berries, the bitter principles of calendula and chamomile, the purgative principle of castor oil, and the acrid principle of mezereon bark. Examinations are required of the red colouring matter of the petals of the poppy and of the active constituents of *Euphorbia pilulifera* and strophanthus. A comparison is desired of the constituents of simarouba bark with those of quassia, also of the two species of cascara sagrada—viz., *Rhamnus purshiana* and *Rhamnus californica*. A systematic examination is needed of damiana, a drug extensively used in the form of an extract of the leaves. It is reported to contain a bitter substance, resins, and volatile oil. The veratrine of the British Pharmacopœia is a mixture of several alkaloids, notably the crystalline veratrine and the amorphous veratridine. The question has not been settled whether pure veratrine might with advantage be substituted for this mixture of potent alkaloids. Apomorphine presents an interesting problem. It is well known that solutions of this alkaloid become coloured on keeping but it is uncertain whether such solutions retain their potency. Of potent drugs that are largely used in medicine, although we have no definite knowledge as to the strength of the preparations made from them, Cannabis indica, jaborandi, and ergot may be mentioned. Ergot is a drug possessing several constituents of different physiological value. Thus, ergotinic acid is soluble in water but insoluble in alcohol and produces paralysis of the spinal cord. Another principle of ergot, sphacelinic acid, on the contrary, is insoluble in water but soluble in hot alcohol and produces contraction of the blood-vessels. A third substance, ergotinine or cornutine, is probably the most important; it causes contraction of the uterus. It would appear to be particularly necessary to possess means of determining the strength of preparations of ergot, at least in terms of ergotinine. The botanical origin of several well-known drugs is still doubtful and requires investigation, the drugs of doubtful origin including the varieties of asafœtida and galbanum, the gum-resin opoponax, and the varieties of copaiba that are met with in commerce. Many of the problems referred to will demand for their solution the collaboration of pharmacologists and pharmacists.

THE TREATMENT OF EPITHELIOMA BY RADIUM.

THE *Clinique Ophtalmologique* of July 25th contains an article by Dr. A. Darier on the Treatment of Epithelioma (Superficial) by Radium. In one case the disease commenced as a hard nodule on the ala of the nose eight years before being seen by Dr. Darier. It was originally treated by the application of tincture of iodine. Two years subsequently it was completely removed by the knife but it reappeared and continued to extend, presenting the characters of a typical epithelioma and affecting the side of the nose, the inner angle of the eyelid, and the outer surface of the lower lid. Dr. Darier applied the galvano-cautery to various points of the edges of the ulcer, then touched them with chromic acid, and finally powdered the surface with methyl blue. The results seemed to be satisfactory and the patient went home. After the lapse of a few months she returned with a trilobate tumour affecting the upper lid and declined to undergo any further operative treatment. Dr. Darier then suggested the employment of radium, which was accepted, and he proceeded to apply to each of the three lobes of the tumour five milligrammes of sulphate of radium of 500,000 units activity attached with enamel varnish to a plate of copper one inch square. The application lasted 90 minutes (30 minutes to each lobe); three days afterwards the exposure was repeated. In the course of eight or ten days the tumour had melted away and only a small ulcer remained. The applications of radium were continued every eighth day and in a month's time a complete cure was effected. There only remained a slight depression and redness of the adjoining skin. Dr. Darier prefers the radium emanations to the x rays on account of their being far more easily managed. The best means of ascertaining the activity of the substance that is about to be used consists in placing it in contact with the skin of the forearm for a period of from five to 20 minutes and noting the number of days that elapse before the redness characteristic of radium is produced. If the radium be pure and separated from the skin by a layer of varnish only the burn may appear immediately. Inclosed in a glass tube it may, if the glass be thick, lose as much as 90 per cent. of its activity. Mica, celluloid, and caoutchouc absorb a much smaller proportion. Dr. Darier uses the sulphate suspended in a varnish which is applied to a metal and strongly heated. This in different strengths he uses for the treatment of epithelioma, chalazion, warts, nævus, trachoma, conjunctival tuberculosis, Parinaud's conjunctivitis, spring catarrh, and certain forms of parenchymatous keratitis. The little apparatus is applied for 20 or 30 minutes every second, third, or even eighth day.

A SANATORIUM FOR CONSUMPTIVE CHILDREN.

MOST of the existing sanatoriums for tuberculous patients receive only adults, but children are, nevertheless, quite as liable to suffer from tuberculous disease and, in fact, have a special predisposition to some forms of it. In the interests of these helpless little sufferers an appeal is being made on behalf of a proposed sanatorium for consumptive children which it is proposed to erect on a site in Norfolk between Holt and Cromer. The list of patrons and the general committee include many well-known and influential names, about half the number being ladies. The intention is to commence with a small building capable of accommodating about 25 children and the necessary staff but so planned as to allow extensions being made when opportunity offers. A sum of £8000 is required at the outset. Donations and subscriptions may be paid to the "Children's Sanatorium Account" at Messrs. Hoare's Bank, 37, Fleet-street, London, E.C., or may be sent to Mr. Thomas H. Wyatt, M.V.O., the honorary secretary, at the temporary address, The Rectory, 42, Great Ormond-street, London, W.C.

"FONDATION OPHTALMOLOGIQUE ADOLPHE DE ROTHSCHILD."

IN a pamphlet of 32 pages Dr. A. Trousseau gives an account of an ophthalmic institute which has been built at Paris at the cost of the late Baron Adolphe de Rothschild who left a large sum for its construction and endowment. It has received the name of "Fondation Ophtalmologique Adolphe de Rothschild" and Dr. Trousseau was named in the will to be the first director. The building was intrusted to two architects who have spared no pains to adapt it in every way to the purpose for which it was designed. A reproduction of a photograph is appended to the pamphlet which shows the façade of a handsome edifice of four storeys with attics. It is situated at the angle of the junction of the Rue Manin and of the Rue Priestley, is in close relation with numerous tramways, and by the metropolitan railway is in connexion with the heart of Paris. It is well lighted, as Dr. Trousseau, who seems to have been consulted largely, is not a believer in darkness in the ordinary treatment of ophthalmic affections. It is 250 feet above the level of the sea and has an area of about 20,000 feet. Behind it is a large garden for the exercise and the recreation of the patients. The hospital looks to the north-east over the park of Buttes-Chaumont and the pleasure ground is therefore to the south-west. The operating theatre faces the north. The drainage and the ventilation have been carefully considered. The floors are of iron covered with cement. An agreeable temperature is maintained by a steam engine working at low pressure. The whole building is freely illuminated by electricity generated on the spot and there are all kinds of electrical apparatus capable of being utilised in the treatment of disease such as is required for galvano-cautery, photophores, and exploratory lamps. Corners and ledges that might harbour dust have been avoided as far as possible. There are a laundry, a disinfecting room, and a destructor for burning all dressings. Radiography can be practised. Every arrangement is made for the sterilisation of instruments, dressings, and for personal cleanliness. The hospital contains 36 beds. There are to be no paying patients. The benefits which it affords are to be open gratuitously to all. A novel and good feature of the service of the hospital is that consultations are to be held three times daily, in the morning from 9 to 12, in the afternoon from 1 to 3, and in the evening for working men who have no other available time, from 7 to 8. The establishment as a whole is worthy of the liberality of the late Baron A. de Rothschild and of the care and attention which have been bestowed upon it by Dr. Trousseau.

THE DISTRIBUTION OF CARBONIC ACID.

To what an extent the health and comfort of human beings depend upon the proportion of carbonic acid gas in the air which they breathe is known to all students of hygiene. In the life of other organisms, also, the substance plays an important part; thus, Brown and Escombe have shown that the living leaf assimilates carbonic acid according to the pressure of the gas in the surrounding atmosphere, while Loeb has demonstrated the influence which the gas exercises upon the occurrence of parthenogenesis. Normally there is present in the air about 0·04 per cent. of carbonic acid and when local interference—e.g., the absence of efficient ventilation—is eliminated this ratio exhibits little variation. All the more curious, therefore, are certain observations upon the composition of the air in the vicinity of the island of Disko which are recorded in No. 26 of *Meddelelser om Grønland.* The island is situated near the west coast of Greenland in a region where there are no artificial conditions likely to introduce atmospheric modifications, yet a Danish man of science, M. A. Krogh, found that at different seasons the proportion of carbonic acid in the air varied from 0·025 to 0·07 per cent., the highest amounts being present when the wind was blowing from the north and west and the lowest occurring in conjunction with southerly and easterly winds. He concludes that the island of Disko must be near the margin of an area in which carbonic acid gas is liberated and as to the source of the supply he offers an ingenious explanation suggested by a circumstance which at first sight appears to have not the remotest connexion with the subject—viz., the thickness of the shells of certain molluscs. Jensen had observed that the calcareous portion of molluscan shells taken from deep water was thin and sometimes eroded as if by the action of some chemical agent and it has also been noted that the shells of dead molluscs falling into deep water are speedily dissolved. These effects it is thought can only be satisfactorily explained by assuming that in the depths of the sea there is much carbonic acid in solution and Krogh has supposed that in Baffin Bay there is an upwardly directed stream of water loaded with carbonic acid, which gas is liberated when the water containing it reaches the surface.

THE STERILISATION OF SO-CALLED DEGENERATES.

WE have received from Dr. R. Rentoul a long communication in reference to our annotation of July 29th entitled "The Sterilisation of So-called Degenerates." On several occasions we have alluded to Dr. Rentoul's views on this topic and as the statement of them which has just been forwarded to us presents no novel features we are unable to find space for more than a brief notice of it. The familiar statistics from the reports of the Commissioners in Lunacy and from other sources are set forth and are made the basis of unconvincing arguments but there is no attempt to formulate a practical scheme for the application of the principle of sterilisation to existing social conditions. There is, on the contrary, a want of clearness as to the matters really at issue which detracts from the value of the suggestions offered. "At present," says Dr. Rentoul, "the ovaries, tubes, and uterus are removed when persons suffer from diseases of those organs," and after mentioning rather superfluously some instances he proceeds: "No one objects to this sterilisation and if we so agree why can we not agree to extend its beneficial action to the prevention of mental diseases?" The cases are obviously not parallel, for in the one the persons operated upon are agreed as to the advisability of the operations, while in the other the agreement, so far as it goes, is merely on the part of those who may be called in to operate. Dr. Rentoul appears to be under the impression that because the provisions of the Lunacy Act, 1890, do not meet the difficulties connected with the segregation of the unfit nothing more can be accomplished in this direction by legislation. For ourselves we are content to wait in order to see what the deliberations of the Royal Commission on the Care of the Feeble-minded may bring forth.

THE RELATIVE VALUE OF BACTERIOLOGICAL AND CLINICAL SYMPTOMATOLOGY.

THE quarantine camp at Tor, a village on the coast of the peninsula of Sinai and not far from Suez, is an important place in connexion with the annual pilgrimage to Mecca. As the risk of the dissemination of epidemic disease by the pilgrims on returning to their homes is recognised even in Mahometan countries, a careful supervision over these travellers is exercised at various points and an outline of the routine work of the camp at Tor last March and April is given in two pamphlets published by the Conseil Sanitaire Maritime et Quarantenaire d'Égypte. One of them is by Dr. Zachariadis Bey, director of the camp in question. On account of the presence of plague in Egypt all the Egyptian pilgrims as well as foreigners passing through Egypt had to undergo quarantine at Tor but no case of the disease was discovered. The prevailing diseases this year were pneumonia and dysentery. The general health of the pilgrims was not so good as last year when there were 79 deaths among 29,964 pilgrims, whereas this year there were 161 deaths among 33,036 pilgrims. Dr. Zachariadis speaks highly of the services rendered by the medical staff which included at least one female practitioner (*doctoresse*). Three bacteriologists were engaged at the camp, one of whom (Dr. Felix Gotschlich) had the special duty of searching for the cholera vibrio and was the author of one of the two pamphlets to which we have referred. The decision as to whether epidemic disease existed among the pilgrims rested with Dr. Zachariadis as being director of the camp and this year, not for the first time, he decided that the presence or absence of clinical symptoms among the pilgrims was of far more diagnostic importance than the bacteriological results, whether positive or negative, obtained in the laboratory. For instance, he states that in 1895 he declared the camp infected with cholera and took measures accordingly some time before the bacteriologists succeeded in finding the cholera bacillus; eventually, however, the bacillus was found. On the other hand, in 1897 he declared the camp healthy although the bacteriologists had found the cholera bacillus; there were then 6000 pilgrims in the camp, none of whom presented symptoms of cholera, and there were no outbreaks of the disease in the places to which they returned in their own countries. During the pilgrimage of the present year a similar conflict of opinion arose. In six fatal cases which after necropsy were officially described as either colitis or dysentery Dr. Gotschlich found a bacillus which in his opinion was beyond all doubt that of cholera.[1]

---

[1] The words of Dr. Gotschlich are as follows, the italics being his own: "En *résumé* il résulte de notre examen approfondi des six cultures en question, d'après les méthodes les plus variées, tant de la séro-réaction que de l'examen des caractères morphologiques, biologiques, et cultureux, que *ces vibrions appartiennent tous à une même et unique espèce et sont tous identiques avec le vrai vibrion de choléra de Koch.*"

Dr. Zachariadis, however, relying on the complete absence of clinical symptoms, declared the camp to be free from cholera and no quarantine restrictions were imposed. Dr. Gotschlich admits that there were no clinical symptoms of cholera among the pilgrims and his explanation of the apparent discrepancy is that the disease was "latent" in these six cases. He quotes an instance of the vibrio of cholera remaining "latent" for 50 days during a patient's convalescence.

THE medical officer of health of Cape Colony states that during the week ending July 15th only 1 new case of plague was discovered in the colony, the patient being a European female at East London. One patient remained under treatment in the hospital at Port Elizabeth and 2 in the hospital at East London. A few plague-infected rats and mice were found at Port Elizabeth, East London, and King William's Town. The commissioner of public health for Queensland, Australia, reports that the last case of plague in Brisbane was discovered on June 14th; on July 1st this patient was discharged from the hospital which was then closed. Among 172 rats and mice which were bacteriologically examined during the week there was no evidence of plague, the last infected rat having been found on June 23rd. At Maryborough in Queensland 10 cases of plague occurred recently but all the patients and "contacts" have now been discharged from the hospital. The Governor of Mauritius has informed the Colonial Office that during the week ended August 4th there were 6 cases of plague reported and 6 deaths occurred.

ON August 14th a donation of 100 francs was sent from the medical officers of the French fleet to the funds of the Royal Portsmouth Hospital. In a note M. le Médecin en Chef H Léo "remercie bien vivement messieurs les médecins de l'Hôpital Royal de Portsmouth, et, avant de quitter le port, il les prie d'agréer, avec les meilleurs souvenirs, la sincère expression de les sentiments reconnaissants et devoués."

THE Umberto I. prize of £200, awarded quinquennially in Italy in memory of H.M. King Umberto I., the subject of the competition being orthopædic surgery, has been awarded to Professor Oscar Vulpius of Heidelberg for his work "Die Sehnenüberpflanzung" (Tendon Transplantation).

METROPOLITAN HOSPITAL SUNDAY FUND.

A MEETING of the council of the Metropolitan Hospital Sunday Fund was held on August 11th, at the Mansion House, to consider the minutes of the general purposes committee recommending: (1) an alteration in the laws of the constitution so as to enable the Queen Victoria Jubilee Institute for Nurses to receive a grant; and (2) an increase in the secretary's salary; also to receive the report of the committee of distribution and to order payment of awards to hospitals and dispensaries.

In the absence of the l [illegible] WATERLOW presided. Among those [illegible] n S. Church, the Hon. Sydney Holland, Sir Stephen Mackenzie, Sir James Ritchie, the Rev. E. H. Pearce, Sir Henry Burdett, Mr. Wakley, Dr. J. G. Glover, Mr. J. Mackrell, Mr. F. H. Norman, Mr. R. B. Martin, M.P., and the Rev. A. A. Harland.

In the annual general report for the year 1905 the committee of distribution recorded with regret the resignation of Captain Cundy who had been an active member of the committee since 1894 and was now unable to give the necessary time to the work of the Fund. Mr. George Herring had again most liberally offered to add one-fourth to the amount collected in places of worship and had also generously extended his offer to amounts collected in the City, whether collected in places of worship or not. The total amount of the Fund at the present time was £61,280, to which had to be added the amount of £12,500 placed at the disposal of the Lord Mayor by the executors of the will of the late Mr. Wyndham Francis Cook in response to the appeal to City men made on behalf of the Hospital Sunday Fund, making a total of £73,780. The committee now recommended the distribution of £71,465 10s. to 162 hospitals and 60 dispensaries. The committee having been unofficially informed that the committee of the City Orthopædic Hospital was prepared to amalgamate with the other two orthopædic hospitals, subject to the seven propositions put forward by King Edward's Fund being somewhat modified, recommended a grant to be made subject to the amalgamation being carried through. The committee desired to impress upon institutions receiving grants from this Fund that awards were made towards the maintenance of patients and not for building purposes. It recommended that in calculating the cost of out patients in future the number of attendances be taken instead of the number of cases. This year 223 institutions had made application for grants from the Fund, being five more than in 1904. One hospital which applied for a grant was considered ineligible. The committee having reduced the bases of award in 27 cases this fact was intimated to each hospital interested in accordance with Rule V Twelve deputations attended the committee and after hearing their cases the final awards were determined. 5 per cent. of the total sum collected was set apart to purchase surgical appliances (in obedience to Law XII.) in monthly proportions during the ensuing year. In compliance with an order of the council and for the special use of its members tables of statistics had been prepared as usual, showing an analysis of the number of beds in hospitals, the cost of patients both at hospitals and dispensaries, and the proportionate expense of management, as well as other valuable information.

On the motion of the CHAIRMAN, seconded by Mr. MARTIN, M P., it was decided to increase the secretary's salary from £400 to £500 per annum.

Mr. F. C. CARR GOMME said that at the last meeting of the general purposes committee a very influential deputation from the Queen Victoria Jubilee Institute of Nurses was received asking that the institute might receive a grant from the Fund. The committee heard of the work which the institute was doing and it was shown that in consequence of its having had to spend nearly all the capital it could part with it would be reduced in future years in its income. The work which the institute was doing was really cognate to the work of the hospitals; and the nurses attached to the institute were able to prevent many cases from coming to the out-patients' departments of the hospitals. By this means they were taking a large part in hospital work; and the committee felt that it would be doing a good thing to include the institute in the Fund. The laws of the constitution did not, however, permit of this being done and he moved that an addition should be made to these laws to the effect that the committee of distribution do put aside a certain sum of money for the purposes of a grant to the Queen Victoria Jubilee Institute of Nurses.

Mr. MARTIN, M.P., seconded the motion, pointing out that a similar course was taken by the Fund in order to include a grant to the Surgical Aid Society.

Mr. MACKRELL did not see how it was logically possible to give a grant to one organisation of nurses and to exclude other organisations

Mr. NORMAN did not see how it would be possible to investigate the efficiency of the work done by nursing institutions in a way analogous to that which the Fund used for testing the efficiency of hospitals.

The Rev. E. H PEARCE moved as an amendment that the matter be referred to the general purposes committee for further investigation

The Hon. SYDNEY HOLLAND agreed that other nurses besides those referred to ought to receive a grant from the Fund. The work of attending to patients both before and after treatment at hospitals by nurses in the districts round London was helpful to the out-patient departments.

Sir HENRY BURDETT seconded the amendment. He said that the work done by district nurses was a useful one and in his opinion the reform which all desired in the out-patient department of hospitals would not be achieved until there was some unifying connexion between the district nurses and the hospitals of the districts in which they worked.

The amendment having been carried was put as the substantive motion and adopted.

The CHAIRMAN moved the adoption of the report. He said that this was the thirty-third year of the *Hospital Sunday Fund*. It was founded in 1872 and the total amount received and distributed by the committee since that date had been £1,382,160. He thought they might say that the Fund had been a great success. The collections this year at present exceeded £75,000 and as the financial year did not end until Oct. 31st a considerable increase on this amount might be expected. The collections in places of worship could not yet be estimated. There were very serious decreases in some of the larger collections but, on the other hand, there were many increases. The sum of £12,500 placed at the disposal of the Lord Mayor for this Fund had established a record year, the amount collected largely exceeding the figures reached in any previous year. Mr. George Herring, to whom this Fund was so much indebted, had this year, in addition to adding one quarter to the amount collected in places of worship, allowed the secretary to state that any money collected in the City should be considered as having been given in places of worship. This year 222 institutions would receive grants, the amount distributed being over £71,000.

Sir JAMES RITCHIE seconded the motion.

Dr. GLOVER asked a question with reference to the expenditure of hospitals and the CHAIRMAN, in reply, stated that the subject was one which was constantly under the discussion of the committee. Everything had been done to induce the hospitals to be as economical as they could, having regard to efficiency.

Mr. MACKRELL also spoke of the work done by the secretary in this respect.

On the motion of Sir WILLIAM CHURCH, seconded by the Hon. SYDNEY HOLLAND, the thanks of the council were accorded to Mr. Herring for his generous and continued interest in the Fund.

Sir HENRY BURDETT proposed, and the Rev. E. H. PEARCE seconded, a vote of thanks to the committee of distribution for the care bestowed by it in the preparation of the awards. Sir Henry Burdett incidentally mentioned that the initiative of the Fund really belonged to the late Dr. James Wakley whose articles in THE LANCET advocated the cause of a Hospital Sunday Fund for the metropolis.

On the motion of the Rev. Mr. HARLAND, seconded by Mr. T. J. WEST, a vote of thanks was given to the editors of newspapers who had pleaded the needs of the hospitals and advocated the cause of the Fund, special reference being made by the proposer to the valuable help given by THE LANCET and the *Hospital*.

A vote of thanks to the Lord Mayor, the Right Hon. Sir John Pound, who as president and treasurer had devoted his valuable time and influence to the well-being of the Fund, was proposed by Dr. GLOVER and carried with acclamation, as was also a vote of thanks to the chairman, proposed by Sir EDMUND HAY CURRIE and seconded by Mr. WAKLEY, who reminded Sir Sydney Waterlow of his meeting the late Canon Miller and the late Dr. James Wakley in the offices of THE LANCET 33 years ago.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

The City of Birmingham.—The report of the medical officer of health of Birmingham, Dr. J. Robertson, on the health of the city during 1904 has just been issued. The year has been memorable as the one during which the supply of pure water from Wales was effected. The birth-rate for the year was the lowest on record, being 31·5 per 1000. The death-rate was 19·3, compared with 17·2, the death rate for 1903. As in previous years the death rate was much higher in the poorer and more congested districts than in the more salubrious parts. In St. Bartholomew's ward the rate was 28·7, whilst in the Edgbaston and Harborne ward it was 12·7. The death-rate among infants was particularly high and showed a similar discrepancy in the different districts. In the Edgbaston and Harborne ward it was 133 per 1000 births, whilst in St. Mary's ward it was 331 per 1000. The zymotic death-rate was 3·44, against 2·32 in 1903. The health of Birmingham during 1904 therefore contrasts unfavourably with that during the previous year. There were eight cases of small-pox notified and, as showing the value of the means provided for such cases, it is interesting to learn that they represented seven separate importations. There was a very satisfactory decrease in the number of cases of typhoid fever, there being only 248 cases against 348 in 1903. An even greater proportionate decrease was also noted in the number of cases of scarlet fever. There was a slight increase in the death-rate from influenza, measles, and tuberculosis. No fewer than 1110 persons died from diarrhœa and 400 died from cancer. Dealing with the housing question, Dr. Robertson states that 1119 houses were reported as unfit for human habitation, as against 304 in 1903, 450 in 1902, 15 in 1901, and none in 1900. Closing orders were obtained in respect of 233 houses, 127 were demolished, and 242 were made fit for habitation. Much excellent work has been done in the way of securing greater cleanliness in the milkshops of the city and no outbreak of disease could be traced to any of the milk-supplies. The report for the half year ending July 1st, 1905, has also been presented and from the general mortality-rate and the absence of serious epidemic disease the health of the city has been better than in any similar period since statistics have been kept. The death-rate was 16·2, compared with 19·8 per 1000 for the same period in 1904. 33 cases of small-pox had been treated at the city hospital, of which 19 were discharged cured and 14 remained in hospital on July 1st. The death-rate for the first week of July was noteworthy as being the lowest weekly rate ever recorded, being 10·6 per 1000. For the second week the death-rate rose to 14.

Wolverhampton County Borough.—The annual report for 1904 on the health of Wolverhampton has just been issued and Dr. H. Malet, the medical officer, is able to make the gratifying statement that of the large towns the death-rates of which are tabulated Wolverhampton was last year thirty-eighth on the list, whereas in 1903 it was eleventh, and in 1902 and 1901 eighth. No death had occurred from measles. The birth-rate was low, 29·8 per 1000; so also was the death-rate (16).

Warwickshire County District.—Dr. A. Bostock Hill, the medical officer of health of Warwickshire, has presented his report for 1904. For the first time for some years he has been able to record an increase in the birth-rate; the increase is due to the higher rate than usual in the urban districts. The death-rate was slightly higher than in 1903 and 1902, being 14·8 as compared with 13·69 and 13·45 respectively for the two previous years. There was an increase in the zymotic death-rate but this was due to diseases over which sanitary authorities have but little control. 73 cases of small-pox had been notified. There had been an increased fatality from diarrhœa and the deaths from whooping-cough were nearly double those recorded in 1903. He attributed the prevalence of the latter disease to the carelessness of parents in not sufficiently isolating children suffering from the infection. The mortality from pulmonary tuberculosis was less than in 1903 but rather higher than in 1901 and 1902. He hoped it would become the habit of all the district councils to offer disinfection by their officers of all houses where deaths occur from this disease.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 7643 births and 5226 deaths were registered during the week ending August 12th. The annual rate of mortality, which had been 13·4, 15·0, and 17·0 per 1000 in the three preceding weeks, further rose last week to 17·5 per 1000. In London the death-rate was 17·3 per 1000, while it averaged 17·5 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 5·0 in Hornsey, 6·6 in Ipswich, 6·7 in King's Norton, 8·1 in Croydon, 8·5 in Walthamstow, 8·7 in Rotherham, 9·5 in West Hartlepool and in Gateshead, and 9·6 in Halifax; the highest rates were 23·0 in Grimsby, 23·4 in Hanley, 23·5 in East Ham, 23·7 in Norwich, 24·4 in Warrington, 24·7 in Birkenhead, 25·5 in Sheffield, 25·8 in Bootle, 26·1 in Merthyr Tydfil, 28·3 in Wigan, and 33·4 in Rhondda. Excluding 29 deaths due to the colliery explosion at Watts Town the death-rate in Rhondda during the week would have been 22·1.

The 5226 deaths in these towns last week included 1626 which were referred to the principal infectious diseases, against 612, 1101, and 1507 in the three preceding weeks; of these 1626 deaths, 1376 resulted from diarrhœa, 77 from whooping-cough, 70 from measles, 47 from diphtheria, 35 from scarlet fever, and 21 from "fever." No death from any of the principal infectious diseases was registered last week in Hornsey or in Burton-on-Trent; and while Croydon, Hastings, King's Norton, Smethwick, Halifax, and Rotherham had the lowest death-rates from these diseases, the highest rates were recorded in West Ham, Norwich, Walsall, Grimsby, Birkenhead, Liverpool, Bootle, Wigan, Manchester, Sheffield, Hull, and Rhondda. The greatest proportional mortality from measles occurred in Barrow-in-Furness, Sunderland, Merthyr Tydfil, and Swansea; from whooping-cough in Hanley and Middlesbrough; and from diarrhœa in West Ham, Norwich, Walsall, Grimsby, Birkenhead, Bootle, Wigan, Sheffield, Hull, and Rhondda. The mortality from scarlet fever, from diphtheria, and from "fever" showed no marked excess in any of the large towns. No death from small-pox was registered last week in any of the 76 towns. No small-pox cases remained under treatment in the Metropolitan Asylums Hospitals at the end of last week. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday last, August 12th, was 2670, against 2485, 2550, and 2632 on the three preceding Saturdays; 355 new cases were admitted during the week, against 304, 352, and 266 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 117, 116, and 111 in the three preceding weeks, were 112 last week, the number in the corresponding period of last year being 121. The causes of 40, or 0·8 per cent., of the deaths in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Portsmouth, Bristol, Nottingham, Salford, and Leeds, and in 46 other smaller towns; while the largest proportions of uncertified deaths were registered in Norwich, Liverpool, Wigan, Blackburn, and South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 15·2, 15·3, and 14·8 per 1000 in the three preceding weeks, further fell to 13·8 per 1000 during the week ending August 12th, and was 3·7 per 1000 below the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 10·8 in Dundee, 11·5 in Aberdeen, and 11·6 in Paisley to 16·6 in Leith and 17·8 in Greenock. The 463 deaths in these towns last week included 44 which were referred to diarrhœa, 10 to whooping-cough, eight to measles, two to scarlet fever, and one each to diphtheria and "fever," but none to small-pox. In all 67 deaths resulted from these principal infectious diseases last week, against 61, 66, and 94 in the three preceding weeks. These 67 deaths were equal to an annual rate of 2·0 per 1000, which was 3·4 per 1000 below the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of diarrhœa, which had been 22, 39 and 59 in the three preceding weeks, fell last week to 44, of which 34 occurred in Glasgow, and two each in Edinburgh, Dundee, Leith, and Greenock. The deaths from whooping-cough, which had been 12, 14, and 14 in the three preceding weeks, were ten last week, and included five in Glasgow and two in Edinburgh. The fatal cases of measles, which had been 21, eight, and 15 in the three preceding weeks, fell to eight last week, of which five were registered in Glasgow and two in Perth. The deaths from diphtheria, which had been three, five, and two in the three preceding weeks, declined to one last week, the fatal case having occurred in Perth. The deaths referred to diseases of the respiratory organs in these towns, which had been 62, 70, and 48 in the three preceding weeks, further fell to 33 last week, but were six in excess of the number in the corresponding period of last year. The causes of two, or 0·4 per cent., of the deaths registered in these eight towns last week were *not* certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 20·1, 20·8, and 21·2 per 1000 in the three preceding weeks, fell to 19·7 per 1000 during the week ending August 12th. During the past four weeks the death-rate has averaged 20·5 per 1000, the rates during the same period being 15·0 in London and 16·1 in Edinburgh. The 143 deaths of person belonging to Dublin registered during the week unde notice were 11 below the number in the preceding week and included 25 which were referred to the principal infectious diseases, against 20, 22, and 29 in the three preceding weeks; of these, 24 resulted from diarrhœa and one from diphtheria. These 25 deaths were equal to an annual rate of 3·4 per 1000, the mean rates last week from the principal infectious diseases being 5·1 in London and 0·8 in Edinburgh. The fatal cases of diarrhœa, which had been 18, 20, and 25 in the three preceding weeks, fell last week to 24. The deaths in Dublin last week included 49 of children under one year of age and 32 of persons aged 60 years and upwards; the deaths of infants and those of elderly persons both showed a decrease from the numbers registered in the preceding week. Three inquest cases and two deaths from violence were registered; and 50, or more than a third, of the deaths occurred in public institutions. The causes of seven, or nearly 5 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

Royal Navy Medical Service.

The undermentioned Surgeons have been promoted to the rank of Staff Surgeons in His Majesty's Fleet, viz.:—Albert Xavier Lavertine (dated May 15th, 1903); John Charles Rowan (dated Nov. 12th, 1903); William Rudolf Center and William Milne Keith (dated May 13th, 1904); Arthur Richard Harrie Skey and Frank Hutton Nimmo (dated Nov. 10th, 1904); and Walter Henry Ormonde Garde (dated May 25th, 1905).

Royal Army Medical Corps.

Colonel (temporary Surgeon-General) W. F. Stevenson, C.B., K.H.S., is placed on retired pay (dated August 1st, 1905). The undermentioned Majors are placed on retired pay (dated August 1st, 1905):—J. H. Brannigan, B. A. Maturin, A. P. H. Griffiths, H. T. Baylor, and W. S. Boles.

Imperial Yeomanry.

Berks: Surgeon-Captain J. H. Waters to be Surgeon-Major (dated August 16th, 1905).

Volunteer Corps.

Royal Garrison Artillery (Volunteers): 1st Norfolk: Surgeon-Lieutenant W. O. Beddard to be Surgeon-Captain (dated August 16th, 1905).

Rifle: 3rd Lanarkshire: John Paton to be Surgeon-Lieutenant (dated August 16th, 1905). 14th Middlesex (Inns of Court): Surgeon-Lieutenant A. M. Ware to be Surgeon-Captain (dated July 24th, 1905).

L'Entente Cordiale.

Portsmouth has given a magnificent reception to the French Fleet and the effect upon our visitors cannot be other than of a happy and abiding character. The spirit of *l'entente cordiale* has again been apparent between the medical men of the two countries. On August 11th a number of the French medical officers visited Haslar, among whom were Dr. Langier, Médecin Principal de la Marine, and Dr. H. Léo, Médecin en Chef, and inspected the various departments of the Naval Hospital. Later in the day they visited the Royal Portsmouth Hospital and were entertained by the medical staff.

The Japanese Red Cross Society.

An article in the *Times* of August 15th on the organisation of the Japanese Red Cross Society will be read with interest by all who are in sympathy with the benevolent work of Red Cross societies. We reproduce the first paragraph:—

> The Red Cross Society of Japan is, by its creation, the last of Red Cross societies, but it is by far the first and foremost of these societies by its splendid organisation, its wealth, and its power for good. The Japanese Red Cross Society had recently 920,000 members; its funds in hand amounted before the war to £794,000; and it possessed an annual income of £231,000. At present it should have about a million members, and its yearly income should be about £300,000. As wages are about five times higher in Great Britain than they are in Japan the value of money is about five times greater in Japan than it is in this country, since a British Red Cross Society of equal importance to that of Japan would require a war reserve of £4,000,000 and an annual income of about £1,500,000, which by-the bye, would be 20 times larger than that of one of the wealthiest of London hospitals. The matchless services of the Japanese Red Cross Society during the present war are too well known to require description and

the few figures given in the foregoing prove how far ahead of all nations is Japan by her Red Cross Society As, owing to Queen Alexandra's generous appeal, this country is at last endeavouring to create a Red Cross service worthy of Great Britain, we might learn from Japan how to organise it, although England originally was Japan's teacher in these matters

"Audi alteram partem"

INEBRIETY A DISEASE AND THEREFORE TO BE TREATED BY THE MEDICAL PROFESSION.

To the Editors of THE LANCET

SIRS,—It is now becoming generally recognised that chronic inebriety is a disease but the majority of medical men have never taken its treatment seriously in hand There are two reasons for this First, the belief that the victim of the drink crave must be removed from his home and placed in some retreat or sanatorium in order that the treatment may be successfully carried out and, second, because the drugs used and the methods of treatment adopted in these highly advertised institutions have been kept secret Both these objections have now been removed The methods of treatment have been published by Dr C A McBride and Mr S. Blackwell Fenn and my own results prove that the treatment can be carried out by the ordinary medical attendant without removing the patient from his own home The hypodermic injection of atropine has undoubtedly a restraining effect upon the craving for alcohol and if with this is administered strychnine a powerful tonic effect is produced which will soon remove the terrible morning depression from which drinkers suffer In addition to this all that is needed is a suitable diet and a medicine by the mouth to correct any disturbance which is hindering the return to health, such as calomel for the liver, bromide and chloral for sleeplessness, or cinchona and capsicum as a pick me up And, indeed these will only be required for the first few days My cases have been treated as out patients, coming to my house twice a day to receive the injections There is in this more than one obvious advantage If a patient will come of his own free will to a medical man's house for treatment it shows that he has a real desire to be cured And, again, if he gives up his drinking habits while in the midst of temptation he is likely to keep straight, avoiding as he does the risk which arises when, after treatment in a sanatorium, the patient returns to the scene of his former temptation

Of course, no treatment will insure that the man will never fall again Neither is it possible to change the drunkard into a moderate drinker If, after being an abstainer for a time, he argues thus with himself, "Now I have lost the craving for alcohol I am like other men and can take a little with safety"—if he acts upon this assumption he will soon find, to his cost, that the old craving will return His only safety lies in being a total abstainer Another advantage of this out patient system of treatment is that it can be applied to the poor as well as to the rich and, again, being carried out by the family medical man, the patient is not a marked man and stigmatised as one who has been in an inebriate home Some of my patients have been treated under most unfavourable conditions but even when living in a common lodging house with its usual surroundings of drink and squalor the craving has gone and the patient has risen above his environment

I should like to see medical practitioners generally taking up the treatment of this disease I am sure much good would result Many an inebriate would be cured and many a man would be saved from falling a victim to the disease For medical men coming into more immediate contact with the results of excess would become exceedingly cautious in prescribing alcohol and would carefully safeguard their patients lest a temporary use should lead to a fixed habit

Nottingham, August 10th, 1905

SANITATION AT ST. MORITZ.

To the Editors of THE LANCET.

SIRS,—It will be a great kindness on your part if you will allow me through your columns to draw the attention of the local authorities of St Moritz, Upper Engadine, to the constant complaints we receive from patients whom we send there regarding the sanitation of the locality. My patients complain of the absolute indifference on the part of the authorities to their complaints about the drainage. One cannot understand why the authorities should be so blind to their own interests as not to take most vigorous precautions to make the sanitary arrangements, especially the drainage, as perfect as possible I have received quite recently a number of letters from patients whom I have hitherto sent to St Moritz inquiring about other winter quarters, basing their objections to return to St Moritz upon the faulty drainage and consequent bad smells which they allege to be the cause of the sore-throats so often seen there. It will be much to the advantage of St Moritz if the local authorities during this autumn will make a thorough investigation and place the whole sanitary arrangements in such a condition as to be above suspicion After this has been done a report should be sent to the medical press in order to prevent the unfavourable impressions now rapidly spreading regarding this famous health resort

I am, Sirs, yours faithfully,
T W PARKINSON.
Sloane-street, S W, August 8th, 1905

HIGH-FREQUENCY CURRENTS FOR INSOMNIA.

To the Editors of THE LANCET.

SIRS,—The treatment of sleeplessness and pain has lately been a subject for discussion I would like to draw the attention of fellow practitioners to the value of the high-frequency currents as an agent for the cure of sleeplessness and the relief of pain I have now had several years' experience of this form of treatment and am fully convinced of its value It may be that the high frequency currents, like other therapeutic departures, have suffered from too enthusiastic testimonies of injudicious friends, but this should not blind us to their true value I have endeavoured to observe their effects with an impartial mind and have no doubt of their real usefulness in certain conditions It is an undoubted fact that they do produce an effect on the functions of the nervous system though it may not be possible to say exactly how this effect is brought about Quite a common experience is that patients under the influence of the high-frequency currents find themselves relieved of sleeplessness Electricity in this form will not, of course, meet a more or less sudden emergency where sleep is absent in consequence of acute pain or severe mental distress In such circumstances one or other of the powerful hypnotic drugs can hardly be avoided But when there is a habit of persistent insomnia the value of the high-frequency currents is considerable After a series of applications varying in different cases from 15 to 40, patients almost invariably acquire the habit of sound sleep. There are also other advantages—that the sleep is natural and refreshing and is not followed by any of the ill effects attached to the use of narcotic drugs To obtain the best results I find it essential to utilise a large output of electricity ranging from 400 to 800 milliampères in men and from 250 to 700 milliamperes in women Used under these conditions I venture to say that the high frequency currents will rarely be employed in vain in cases of insomnia due to mental worry and other allied conditions

With regard to the use of the high frequency currents in the relief of pain—here again they can hardly compete with morphine in the promptness with which it overcomes pain due to acute inflammation Nor are they generally capable of allaying the acute pain of organic disease But in the treatment of various neuralgias their value is considerable. In neuralgia of the face and forehead and in intercostal, brachial, and sciatic neuralgias I have repeatedly proved their efficacy. The same is true of lumbago and of muscular rheumatism in various parts of the body In reference to sciatica, it is necessary to remember that when the condition depends upon perineuritic adhesions the high frequency currents render little or no help It is because this is not invariably recognised that disappointment has sometimes resulted. But with a true neuritis or with a pure neuralgia the high-frequency currents may be confidently counted upon after a few applications to produce permanently beneficial results In all these instances the method of treatment has the advantage of being grateful and not disagreeable to the patient and in addition it may be stated that the high-frequency currents form one of the best nervine tonics, and therefore while they cure insomnia and relieve pain they also at the same time greatly improve the general nervous condition of the patient. I have never had experience of any unpleasant or injurious effects resulting from the careful application of the high-frequency currents.

It may be advisable here to remark that the treatment by high-frequency currents should be intrusted to qualified medical practitioners only and that it is unwise and irregular for members of our profession in practice to send their patients for any form of electrical treatment to the various unrecognised electrical institutes which are advertised in the lay press.

I am, Sirs, yours faithfully,

Glasgow, August 14th, 1905. W. F. SOMERVILLE, M.D. Glasg.

SECONDARY FACTORS IN THE MORTALITY AND TRANSMISSIBILITY OF PULMONARY TUBERCULOSIS.

To the Editors of THE LANCET.

SIRS,—With regard to my preliminary note on Secondary Factors in the Mortality of Pulmonary Tuberculosis, of which you have kindly published a summary in your issue of July 8th, p 98, I beg to point out that in my last letter I must have left out the words "*per se*" after "pure culture" and "healthy" before "pulmonary tissues" in the wording of the aphorism which you have quoted and which should read: "That the tubercle bacillus in pure culture, *per se*, is incapable of developing in the healthy pulmonary tissues either the anatomical lesions or the clinical symptoms of confirmed pulmonary tuberculosis."

I am, Sirs, yours faithfully,

Havana, July 21st, 1905. CARLOS J. FINLAY.

MISTAKES IN THE DIAGNOSIS OF INFECTIOUS DISEASES.

To the Editors of THE LANCET.

SIRS,—A few years before the last small-pox epidemic I was called to see a man in South Hornsey, North London, suffering from ordinary febrile symptoms, plus a rash, just beginning to appear. The man had been working in St John's Wood. I diagnosed variola as probable and without waiting for any further development I had the man removed and isolated. The case turned out to be virulent small-pox and owing to my promptness the disease never spread to even a member of the family and was stamped out there and then. I risked the "mistake" and saved the ratepayers a large sum of money. For many years where children are swarming in any house and one is down with some supposed infectious disease, to save lives and to save the ratepayers, it has been my custom to have the patient removed *within a few hours after examination*. I risk the "mistake," and if I am wrong in my opinion once in 15 times—about the average for each of us medical men—the saving to the community after deducting the cost of "mistakes" must be enormous.

Yesterday I was called to see a child, aged five years. Apparently typical scarlet fever. House full of children. Mother informs me, when I tell her I shall have her child removed in a few hours, that the boy has only just come home four days from the fever hospital convalescent from scarlet fever! I nevertheless act with my usual promptness and I risk the "error" again to save both lives and the pockets of the already over-burdened ratepayers. In a few hours the child was once again back in his old hospital.

If medical men, through these grossly unjust remarks about their mistakes, will stand, in future, on their rights and wait till the disease is fully developed and infection has spread, instead of a loss to the ratepayers of £12,000 the reckoning will be nearer £120,000. I calculate that after deducting the cost of my "mistakes" the various parishes that I have to do with have been saved at least £10,000 by

Your humble servant,

Endymion-road, N., August 15th, 1905. SAML. CONSTABLE.

THE SPA TREATMENT OF CIRCULATORY DISORDERS.

To the Editors of THE LANCET.

SIRS,—I have read with great pleasure the long and able article by Dr. Leonard Williams on the Spa Treatment of Circulatory Disorders in THE LANCET of August 5th, p. 347, and whilst agreeing with him in the main points of his arguments I must take exception to his statement that effervescent baths can be equally well applied at home. The natural waters containing bicarbonate of iron, calcium and sodium chlorides, &c., are capable of holding a much larger proportion of carbonic acid gas than those artificial waters where the CO_2 has been dissolved by pressure, as in the natural waters the gas has been under pressure for some considerable time. This can be proved by the fact that a bottle of soda water when opened soon loses its CO_2 under normal atmospheric pressure alone and if heat be subsequently applied very little more gas can be driven off. On the contrary, if a natural gaseous water be exposed to the air the greater proportion of CO_2 can only be driven off by the aid of heat.

I have lately returned from a visit to Spa, Belgium, where there exists an ideal supply of effervescent ferruginous water which is brought to the bath house by a conduit and supplied directly to the various baths and when heated by means of steam the quantity of CO_2 driven off is enormous. Whilst at Spa I was shown over the establishment and purposely picked out indiscriminately four different baths and found the effects identical in all.

Dr. Williams mentions Nauheim as the pioneer with its long 24 hours' journey, truly an undertaking not lightly to be considered by a cardiopath, Royat, Contrexéville, and many others equally far distant, but he has altogether omitted any mention of the town of Spa itself in Belgium, only 11 hours from London and reached by a very comfortable route where the treatment is receiving the greatest attention in a most luxurious establishment fitted with all the latest appliances. The climate, unlike Nauheim, is perfection, with bracing air, and the town, facing south, is particularly well sheltered by surrounding hills where delightful scenery abounds; and lastly, the mental comfort of the patient is catered for by excellent arrangements of concerts, race meetings, and a hundred other amusements.

I am, Sirs, yours faithfully,

Stony Stratford, August 8th, 1905. P. LAKE HOPE.

A POSSIBLE CAUSE OF CHLOROFORM FATALITIES.

To the Editors of THE LANCET.

SIRS,—Some time since, when seeking for tests whereby organo-therapeutic substances might be recognised, I found that some of them had an extraordinary power of decomposing chloroform when in solution, chlorine gas becoming rapidly evolved. In the recently published report of Merck Trillat ascribes a similar property to many organic substances, and it is suggested that as the dangerous body phosgene is formed by the contact of chloroform with the human skin it may also arise from contact with the mucous membranes in certain conditions. It seems probable then that in such circumstances the mucous membrane of the respiratory tract may have the power of decomposing chloroform, and where chlorine gas is liberated a fatal result is not to be wondered at.

I am, Sirs, yours faithfully,

J. C. MCWALTER, F.F.P. & S. Glasg., M.D. Brux.

August 12th, 1905.

MIDGES.

To the Editors of THE LANCET.

SIRS,—At this holiday season I should be grateful if you would allow me some space in your columns to elicit the opinions of your readers about midges and their bites. These small pests seem to be particularly active this year and their bites certainly give rise to an immense amount of œdema and irritation. I have seen people, both men and women, with swellings on their ankles, wrists, and neck just above the collar, varying in size from a hazel-nut to a walnut. Has the nature of the poison injected by these insects ever been worked out? Is there anything which will keep them away short of a thick coating of grease, which is impossible in this land? And can anything be done to lessen the irritation, which in my own case lasts for about a week? I might add that I myself am not particularly susceptible to insect bites. Although I have travelled a good deal in the East, mosquitoes, bugs, and lice never gave me any trouble.

I am, Sirs, yours faithfully,

M.D.

August 15th, 1905.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Infantile Mortality in Cheshire.

ACCORDING to the interesting report by Mr. F. Vacher on the health of Cheshire in 1904 there is still scope for much sanitary work. The infantile death-rate in many of the municipal boroughs is far too high, being 24 per 1000 births more than in the 76 great towns in the kingdom, while in the county it was 2 per 1000 births fewer than in the whole country. The highest rate was in Hollingworth urban district where it was 228, Compstall, near Stockport, coming next with 222, while the lowest in the list are the borough of Crewe and Wallasey urban district, each with an infantile death-rate of 159. Speaking generally, it appears that it is highest in the manufacturing districts where the mothers often work in the factories very nearly up to the time of their confinements and where they are at work again too soon afterwards. This, however, is not the only factor. In Macclesfield, where the rate is 178, the local medical officer of health finds that the mortality increases in the warm weather from conditions favouring the growth of micro organisms which cause putrefaction in the food of the infants. Following the example of Manchester there is at Macclesfield a Ladies' Public Health Society for which he asks support. The functions of the society are to visit the house where a baby is born; to take an interest in the child's welfare, and to direct the mother as to the care, feeding, and management of the infant, and as to the necessity for cleanly surroundings. Much may be done by kindly and sympathetic tact on the part of the would-be instructors of their poorer sisters who, as a rule, are *not* wanting in a certain independence and often, indeed, are imbued with a delicacy of feeling little suspected by their visitors. The medical officer of the Northwich urban district does not think the high death-rate of the towns is due to ignorance as its main cause, for it is lower in rural districts though, as a rule, he considers townfolk better educated and with greater facilities for getting help and advice. He points to the keener struggle for existence in the towns and to the fact that town infants are often ill provided with fresh air and sunlight because rents are cheapest in the more crowded courts and alleys. He says also that "soothing syrup and mothers' friend" are more used in the town than in the country. "An infant is more in the way and more costly in town than in the country, and unless some relaxation be made as regards taxation in favour of the man with a family, children will be less cared for." Perhaps some of our politicians in want of a new cry will exploit this idea. Drink and the poor milk-supply contribute their share. Mr. Vacher says that the medical officers of health consider that more prominence should be given in the elementary schools to the teaching of personal and domestic hygiene. This might no doubt be done and it would benefit the coming generations, even if in order to find time for it the curriculum were to lose some of its useless and merely decorative redundancies. The main causes of a high infantile death-rate are summed up as: (1) the employment in factories of those about to become mothers and of those recently confined who should be nourishing their infants; (2) the infants of mothers employed in factories being badly cared for and ill fed while the mothers are at work; (3) the environment being insanitary from the storing of garbage and filth close to the house and the absence of proper paving of yards leading to soil pollution; (4) there being no provision for isolating infectious children or disinfecting bedding, &c.; and (5) the ignorance common among working women as to the feeding, clothing, and management of infants.

House-flies and Diarrhœa.

Dr. J. Niven, the medical officer of health, has given to the sanitary committee a statement of the conclusions arrived at in 1904 as the result of his inquiries into a number of cases of fatal diarrhœa in infants. Under 4 per cent. of these cases had been fed at the breast. The lesson given is therefore that mothers should not wean their babies in the warm months but in order to suckle them they should feed adequately, for "it is cheaper as well as better to spend additional money in feeding the mother than in feeding the infant." Over one-third of the cases specially investigated in 1905 are believed to be due to direct infection from those suffering from diarrhœa or having charge of children suffering from it, therefore no person having diarrhœa should take charge of, or be in the same room with, an infant. There is reason to believe that the great increase of fatal diarrhœa in summer and autumn is due to its spread by house-flies, so that the utmost care should be taken to guard all food, especially that of infants, from their visits. All food, therefore, milk, bread, sugar, syrup, or treacle, should be carefully covered or kept in a safe. Dr. Niven very properly objects to the gums of infants being rubbed with the finger, often a dirty finger, with the idea of easing the gums, for there is reason to believe that diarrhœa is often communicated in this way. On the other hand, the mouth may be usefully swabbed out with a little clean lint dipped in a solution of boric acid after each meal. He objects also to the "dummy teat" which is liable to contamination from dropping on the floor. He also advises that yards should be kept clean and the drains flushed daily, that ash-tubs should not overflow, and that vegetable refuse should not be put into them. All such refuse as tea leaves, cabbage leaves, potato peelings, &c., should be burned in the kitchen fire. Any offensive smell the cause of which cannot be ascertained and removed should be reported at the sanitary office. The poor of Manchester can obtain diarrhœa mixture free of charge at the several police and fire stations. As would be expected, diarrhœa is rapidly increasing at present and it is to be hoped that Dr. Niven's words of good counsel will become widely known and acted on. The war against mosquitoes which seemed so utopian until recently is already bearing good fruit and in like manner we may have to wage deadly war not only against the house-fly but against many others. Should this ever be carried out successfully it will be interesting, and perhaps important, to learn what effect it has on the "balance of nature." Just now Trafford-park is suffering from a plague of small black flies which a few days ago were said to hang over it like a pall and to be a source of much annoyance to the people.

Children's Hospital.

The residuary legatees under the will of the late Mr. Godfrey Ermen have made a donation of £12,000 to the Children's Hospital. It is to be applied to providing a new dispensary and out-patients' department and will, it is believed, substantially cover the cost, leaving the funds contributed by various helpers available for the other objects of the appeal. The maintenance of the new dispensary will necessarily be more costly than that of the old one, so that further donations to the fund are desired. The name of Mr. Godfrey Ermen is to be associated with the new building.

Small-pox in Cheshire.

The papers record a case of small-pox in this place or that but it is not till these various outbreaks are collected together and counted up that the prevalence of the disease is brought home to the mind. In 1904 outbreaks occurred in all the municipal boroughs of Cheshire but Crewe, in 15 of the 36 other urban districts, and in five of the 12 rural districts. Macclesfield reported the highest number—49 cases. Hyde came very near with 46 and Dukinfield had 36 cases. An important part in spreading the disease was, in Cheshire as elsewhere, taken by tramps and common lodging-houses. Mr. Vacher speaks strongly on this danger to the community. The public-houses, too, especially in poor neighbourhoods, frequented by travelling tinkers, knife-grinders, and pedlars, are, by harbouring such people, to some extent instruments for spreading the disease. So, also, the mild cases, not seen by a medical man and not notified, are a source of danger, and likewise those cases which not infrequently have been thought to be chicken-pox. The picking and sorting of waste rags are occasionally responsible (as at Bollington) for conveying infection. In our eminently unpractical country it seems almost hopeless to look for the good of the majority to be considered if it involves any apparent lack of tenderness to the views of faddists and cranks. Otherwise we should by means of vaccination and revaccination be as free from small-pox as is the German army.

When the Electricity Supply System is a "Nuisance."

Some time ago the electricity committee of the corporation was mortified at the result of an action brought against the corporation in the King's Bench Division when its system of electric supply was pronounced to be "itself a nuisance." Now the Court of Appeal says that the verdict went too far, that the rights to break open the streets, to lay and to maintain electric cables, and to convey and to store the electric energy therein, were authorised and protected by the statutory powers of the corporation and it was only when the electric current was allowed to leak and to do damage that a nuisance was set up which was not protected; that what happened in this case, where considerable damage was done to a warehouse, constituted a nuisance for which the corporation was responsible and that there was sufficient evidence of negligence on the part of the corporation or its servants to justify the judge in the King's Bench Division in leaving the question of negligence for the consideration of the jury. In this action substantial damages were given to the plaintiffs. It is said that the committee is not likely to proceed further in the matter. After all, there is some comfort in the thought that if the corporation, with the aid of its "electric supply system," blows up a house or warehouse, with or without injury to those on the premises, the "system" may be called a "nuisance" and may be proceeded against with some chance of success.

Isolation Hospital for Preston.

On August 10th the foundation-stone of a new isolation hospital at Preston was laid by Dr. Brown, chairman of the health committee. It is expected to cost £20,000, and is to be provided with two pavilions for scarlet fever patients, one for diphtheria and one for typhoid fever. There are to be 56 beds, or about one for every 2000 inhabitants.

August 15th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Observations of the Medical Officer of Health of Liverpool upon the Report of Dr. R. J. Reece to the Local Government Board on Small-pox and Small-pox Hospitals at Liverpool, 1902-03.

THE port sanitary and hospitals committee of the Liverpool corporation on March 30th, 1905, had under consideration the report of Dr. R. J. Reece to the Local Government Board on small-pox and small-pox hospitals at Liverpool, 1902-03, and passed the following resolution:—

> That the medical officer be requested to furnish the committee with his observations upon the report.

In pursuance of that resolution Dr. E. W. Hope submitted some observations, a summary of which is appended. Dr. Hope said that the investigations made by Dr. Reece extended over nearly 12 months—namely, from March, 1904, to February, 1905, and he devoted the closest personal attention to those aspects of the outbreak respecting which the Local Government Board desired information and which may be presumed to be those dealt with in the report. After mentioning the area of the city—viz., 23 square miles, with a population of 723,430—an acknowledgment is made of the cordial coöperation and assistance given locally in the course of the investigations. Dr. Hope arranged that every book and every record should be placed at Dr. Reece's disposal, also that every member of the staff whom he desired to interview should be available for the purpose. After these preliminaries Dr. Reece's report proceeds to deal with three important matters connected with the outbreak—viz., (1) the administrative arrangements available for dealing with importations of small-pox into the city and for preventing and limiting its spread; (2) the administration of the hospitals; and (3) the influence exerted by the hospitals themselves in the diffusion of small-pox by what has been called "aerial convection." Dr. Reece mentions that Liverpool as a great seaport town has been especially prone to receive small-pox and regarding the action of the health committee in combating the disease and in promoting vaccination and revaccination he speaks in terms of praise. Want of practical experience of the sanitary administration of cities, Dr. Hope says, has led Dr. Reece to make observations which convey a wrong impression. His complaint on p. 4 of his report that no list had been kept of "contacts" placed under observation suggests a laxity which did not occur. The addresses not only of "contacts" but of all out-workers, with all the names necessary, were carefully kept and each officer engaged in visiting them had been duly recorded, together with his visit in his work books. Dr. Hope gives a facsimile of the record sheets in Appendix B of his observations. These sheets were at Dr. Reece's disposal. On p. 7 of his report Dr. Reece complains that the names of patients are not recorded in a particular book, a book, it may be observed, which was not intended for their record. But there were placed in his hands volumes in which the name, age, address, and date of every patient are recorded, one of them being a volume especially kept for that purpose and the other being a book recording the admission of patients to hospital. It is not apparent therefore why a complaint of this character is made. Dr. Reece complains on p. 10 of his report that spot maps of disease were not made systematically in the health department. It is not quite clear in Dr. Hope's mind what he means by this, whether or not it is inferred that spot maps of disease are made in other places but not in Liverpool. His remark appears to Dr. Hope to arise from a misapprehension of the objects aimed at by medical officers of health in preparing spot maps. They are only prepared when some useful purpose would be served by their preparation and when such maps are necessary to explain or to simplify reports which might otherwise be obscure. Dr. Reece criticises the methods in which the hospital registers and books were kept and suggests that they may be due to the want of previous experience and the short stay of the resident medical officers at the hospitals. Dr. Reece says: "In this report the city hospitals receiving small-pox cases are alone dealt with, but it is manifest that the scheme of supervision of the whole of the city hospitals merits the attention of the hospitals committee of the corporation." This observation, suggesting negligence on the part of the hospitals committee, Dr. Hope says is too general to admit of comment. Dr. Reece, he says, does not appear to have visited these institutions or to have taken steps to acquaint himself with the method of their supervision. Dr. Reece also observes on p. 6 of his report that the medical officer of health has no direct administrative control over the various city hospitals, to which Dr. Hope replies that no one with practical knowledge of the sanitary administration of large cities like Liverpool would suggest that the medical officer could possibly exercise direct administrative control over the city hospitals. In smaller districts it can take place with advantage but in the large cities it would be impracticable. Dr. Hope devotes a large part of his "observations" in questioning Dr. Reece's remarks on the alleged influence of the small-pox hospitals in disseminating the disease, otherwise known as the theory of aerial convection, and says that if Dr. Reece's assertions are well founded the hospital for small-pox erected upon a site carefully selected for the purpose and approved by the Local Government Board, after full and complete inquiries by the Board's experienced inspectors, must be closed as a public danger. Dr. Hope challenges Dr. Reece's findings and questions the statements and diagrams by which the theory of aerial convection was supported with reference to the small-pox hospitals of the city. One of Dr. Hope's strongest arguments against this theory lies in the fact that the invasion by small-pox of houses near to the Fazakerley hospital was least when the hospital had most patients. Dr. Hope also emphasises the fact that no hospital had so many surrounding cases of small-pox as one which itself never received a small-pox patient. In reference to Dr. Reece's remarks on p. 9 of his report, stating that "the generally accepted and, so far as I am aware, the only completely satisfactory explanation of the peculiarities of small-pox incidence around hospitals receiving acute cases of the disease is dissemination of infection by aerial convection," Dr. Hope replies that "it must at once be pointed out that the statement that the theory is generally accepted is without justification. The theory is not generally accepted by experts; it is not generally accepted by medical officers of health, and it has been rejected by the High Courts of Justice both in Ireland and England when the theory had been put forward to restrain the use of certain sites for small-pox hospitals." Dr. Hope concludes his "observations" by saying that "neither the Local Government Board nor the port sanitary and hospitals committee could assent to the continued use of the Fazakerley hospital if the allegations contained in Dr. Reece's table are to be regarded seriously." "The committee will, of course, appreciate that Dr. Reece's report derives its importance from the official position which he holds, and although it does not appear that the Local Government Board have adopted the report, or have given official acceptance to it, yet no doubt must be allowed to remain as to the views of the Board and the views of the committee in the matter."

(FROM OUR OWN CORRESPONDENTS.)

Hospital Treatment of Mental Affections.

Mr. John Carswell, who is certifying medical officer in lunacy cases for the Glasgow parish council, has been pointing out that with respect to applications made to the inspector of poor on behalf of persons supposed to be insane a sorting-out process is necessary in the interests both of the public and of the patients. This can only be done by two methods: first, by a careful medical examination of each case; and, secondly, by provision of a special hospital for the care of the early and transient mental cases. There must necessarily be a considerable proportion of cases presenting mental symptoms which do not require asylum care. He strongly objects to the term "observation wards" as applied to mental hospitals. It leads to the idea that patients are sent there for the purpose of diagnosis, which is not the case. The diagnosis has to be made, if possible, before the patient arrives there. In the Glasgow Hospital the period of residence is limited to six weeks, at the end of which time the patient must be discharged or be certified for the asylum, boarded out, or otherwise disposed of under the lunacy statutes. The patient has perfect freedom of action and there is no power of detention. The hospital is in the midst of a busy district but that causes no difficulty as regards the efficient care and medical treatment of the patients and a certain amount of open-air exercise can be secured. Moreover, the wards are well ventilated and have abundance of light. The average period of residence is about four weeks. Out of 1027 cases reported to the inspector of poor as lunatics 449 were certified insane and were removed directly to the asylum. Of those treated in the mental hospital there were afterwards certified insane and removed to an asylum 134. There were treated in the hospital in addition to those enumerated as having been transferred to the asylum 338. Of these, 213 were discharged recovered, 95 were discharged relieved—i.e., sufficiently well to be sent home or so far recovered from the mental condition as to be cared for in the ordinary wards of a hospital—and 30 had died. There were otherwise disposed of as not certifiable, treated at home, &c., 76. The general result is that of 1027 cases 583 were removed to asylums and 414 were disposed of without recourse to asylum care. The figures seem to justify the general proposition that in a population such as that of Glasgow there is a considerable number of patients who are suitable for treatment in a mental hospital and who could therefore be spared the stigma of being sent to an asylum.

Munificent Gift to Glasgow.

Glasgow has profited much by the gifts of many of her public-spirited citizens and the last possession which she has acquired in that way is by no means her least valuable one. Mr. A. Cameron Corbett, M.P., has notified the Lord Provost that he has agreed to purchase a part of Ardkingloss estate with a view to handing it over to the corporation of Glasgow. The extent of the land in question is 9000 acres and the estate is most exquisitely situated between Loch Long and Loch Goil. As Mr. Corbett says in his letter, his object is "to preserve a grand and rugged region for the best use of those who love the freedom of the mountains and wild natural beauty." In the deed of conveyance a clause is inserted prohibiting the sale of alcoholic liquor and Mr. Corbett suggests that nothing should be done which would mar the naturalness of such scenery. Such a gift is unique and it seems almost unnecessary to descant upon the generosity which prompted it. The corporation has not yet seriously approached the problem of what to do with its new estate but the suggestions put forward by correspondents in the newspapers are legion. Glasgow has hitherto done well in its efforts to provide facilities for those of its citizens who suffer from pulmonary tuberculosis. The work carried on at Bellefield Sanatorium has been largely successful but unfortunately the accommodation there is limited and many patients suitable for treatment are constantly waiting for admission. That this should be so is distinctly unfortunate in the case of a disease in which it is recognised that to obtain the most successful results treatment should be commenced as soon as the disease makes itself manifest. It has been suggested for some time that it would be an advantage to establish a subsidiary sanatorium in the form of a consumptive camp, but one of the difficulties has been to secure a suitable site for such an enterprise. Surely in this large tract of land so generously placed in the hands of the corporation a nook will be found suitable for the establishment of such an institution in a situation where its presence will not interfere with any other plans which may be carried out in order to enable the citizens to take the best advantage of their new possession.

"Tuberculosis and a Simple Life": Lecture by Sir James Grant.

Sir James Grant, M.D., ex-President of the Canadian Association for the Prevention of Tuberculosis, delivered a very interesting lecture in the Young Men's Christian Association Hall, Aberdeen, on August 10th on Tuberculosis and a Simple Life. Dr. J. C. Ogilvie Will presided over a large attendance. Sir James Grant said he was not there as a foreigner but as a Scotchman born and educated in that country. He had merely come from Canada, endorsed by Lord Strathcona, to offer a few observations upon tuberculosis and a simple life, to compare notes with the leading authorities in this country, and to see what could be accomplished by exchange of ideas on those points. After referring to the work of the Canadian Association for the Prevention of Tuberculosis, he said that in mastering or controlling this disease it was absolutely necessary that there should be thorough organisation. Three specific objects were: first, educational; second, preventive; and third, curative. In an educational way a great work was being done by lectures. Then the dissemination of literature was giving people information. With regard to preventive measures, a by-law had been recently passed in Ottawa making it an act for which an individual would be punished—in fact he might be put in prison—if found expectorating in the streets, or on the railways, or in the churches. As regarded curative measures, he said if there was any subject that concerned the welfare of the community it was this matter of the treatment of tuberculosis. They knew perfectly well that sanatoriums were being discussed and erected almost all over the world at the present time. He did not approve of large sanatoriums. Was it to be supposed for one moment that a large number of people huddled together had the same prospect of recovery as by the modern treatment which was going on to-day in the tent and the home? If anyone in the country developed this disease all he had to do was to put up a small tent, fit it up with a bed, a stove, and culinary apparatus, and get the fresh air and modern attention. The house where a consumptive case had been ought to be purified thoroughly and when there was a consumptive patient in the house the health authorities should be notified. He thought a proprietor should be fined if he allowed a second inmate into a house where a consumptive had resided until it was purified thoroughly. The reason why so many took the disease was that their vitality was lowered. If the simpler life was not followed there was danger of a lowered vitality and there would be promoted very readily that condition of the system which would enable the bacillus to settle down and generate tuberculosis. He believed that all schools should be examined by medical experts. The whole question of the treatment of this disease required to be taken into serious consideration by the authorities. Dealing with the question of food and alcohol, he said as regarded food that there was no substance in the whole list of articles of diet that could surpass oatmeal. With reference to the drink problem he was pleased to know that at the present time a marvellous change had been coming over the minds of the people of the world in regard to this extremely important subject. The subject had been carefully, solidly, and substantially investigated. Every day it was growing more popular not to use alcoholic liquors. The lecturer then referred to an interesting visit which he paid to Balmoral and said that he had been thoroughly impressed with the remarkable evidence in all the surroundings of Balmoral of a simple life that contributed in no small degree to lengthen the years which enabled Her Majesty the late Queen Victoria, as woman and sovereign, to influence for good all movements of her time, as if by a unique magnetic power, transmitted to all parts of her empire, throughout which "she made herself understood, beloved, and revered." Dr. Ogilvie Will moved a vote of thanks to Sir James Grant for his excellent address. The subject was one of extreme interest to everyone, to the highest as well as to the lowest in the land. King Edward himself had initiated a home for the treatment of consumption. A great deal had been said as to the establishment of homes for the treatment of tuberculosis amongst convey and to store the electric energy therein, were authorised and protected by the statutory powers of the corporation and it was only when the electric current was allowed to leak and to do damage that a nuisance was set up which was not protected; that what happened in this case, where considerable damage was done to a warehouse, constituted a nuisance for which the corporation was responsible and that there was sufficient evidence of negligence on the part of the corporation or its servants to justify the judge in the King's Bench Division in leaving the question of negligence for the consideration of the jury. In this action substantial damages were given to the plaintiffs. It is said that the committee is not likely to proceed further in the matter. After all, there is some comfort in the thought that if the corporation, with the aid of its "electric supply system," blows up a house or warehouse, with or without injury to those on the premises, the "system" may be called a "nuisance" and may be proceeded against with some chance of success.

Isolation Hospital for Preston.

On August 10th the foundation-stone of a new isolation hospital at Preston was laid by Dr. Brown, chairman of the health committee. It is expected to cost £20,000, and is to be provided with two pavilions for scarlet fever patients, one for diphtheria and one for typhoid fever. There are to be 56 beds, or about one for every 2000 inhabitants.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Observations of the Medical Officer of Health of Liverpool upon the Report of Dr. R. J. Reece to the Local Government Board on Small-pox and Small-pox Hospitals at Liverpool, 1902-03.

THE port sanitary and hospitals committee of the Liverpool corporation on March 30th, 1905, had under consideration the report of Dr. R. J. Reece to the Local Government Board on small-pox and small-pox hospitals at Liverpool, 1902-03, and passed the following resolution :—

> That the medical officer be requested to furnish the committee with his observations upon the report.

In pursuance of that resolution Dr. E. W. Hope submitted some observations, a summary of which is appended. Dr. Hope said that the investigations made by Dr. Reece extended over nearly 12 months—namely, from March, 1904, to February, 1905, and he devoted the closest personal attention to those aspects of the outbreak respecting which the Local Government Board desired information and which may be presumed to be those dealt with in the report. After mentioning the area of the city—viz., 23 square miles, with a population of 723,430—an acknowledgment is made of the cordial coöperation and assistance given locally in the course of the investigations. Dr. Hope arranged that every book and every record should be placed at Dr. Reece's disposal, also that every member of the staff whom he desired to interview should be available for the purpose. After these preliminaries Dr. Reece's report proceeds to deal with three important matters connected with the outbreak—viz., (1) the administrative arrangements available for dealing with importations of small-pox into the city and for preventing and limiting its spread; (2) the administration of the hospitals; and (3) the influence exerted by the hospitals themselves in the diffusion of small-pox by what has been called "aerial convection." Dr. Reece mentions that Liverpool as a great seaport town has been especially prone to receive small-pox and regarding the action of the health committee in combating the disease and in promoting vaccination and revaccination he speaks in terms of praise. Want of practical experience of the sanitary administration of cities, Dr. Hope says, has led Dr. Reece to make observations which convey a wrong impression. His complaint on p. 4 of his report that no list had been kept of "contacts" placed under observation suggests a laxity which did not occur. The addresses not only of "contacts" but of all out-workers, with all the names necessary, were carefully kept and each officer engaged in visiting them had been duly recorded, together with his visit in his work books. Dr. Hope gives a facsimile of the record sheets in Appendix B of his observations. These sheets were at Dr. Reece's disposal. On p. 7 of his report Dr. Reece complains that the names of patients are not recorded in a particular book, a book, it may be observed, which was not intended for their record. But there were placed in his hands volumes in which the name, age, address, and date of every patient are recorded, one of them being a volume especially kept for that purpose and the other being a book recording the admission of patients to hospital. It is not apparent therefore why a complaint of this character is made. Dr. Reece complains on p. 10 of his report that spot maps of disease were not made systematically in the health department. It is not quite clear in Dr. Hope's mind what he means by this, whether or not it is inferred that spot maps of disease are made in other places but not in Liverpool. His remark appears to Dr. Hope to arise from a misapprehension of the objects aimed at by medical officers of health in preparing spot maps. They are only prepared when some useful purpose would be served by their preparation and when such maps are necessary to explain or to simplify reports which might otherwise be obscure. Dr. Reece criticises the methods in which the hospital registers and books were kept and suggests that they may be due to the want of previous experience and the short stay of the resident medical officers at the hospitals. Dr. Reece says: "In this report the city hospitals receiving small-pox cases are alone dealt with, but it is manifest that the scheme of supervision of the whole of the city hospitals merits the attention of the hospitals committee of the corporation." This observation, suggesting negligence on the part of the hospitals committee, Dr. Hope says is too general to admit of comment. Dr. Reece, he says, does not appear to have visited these institutions or to have taken steps to acquaint himself with the method of their supervision. Dr. Reece also observes on p. 6 of his report that the medical officer of health has no direct administrative control over the various city hospitals, to which Dr. Hope replies that no one with practical knowledge of the sanitary administration of large cities like Liverpool would suggest that the medical officer could possibly exercise direct administrative control over the city hospitals. In smaller districts it can take place with advantage but in the large cities it would be impracticable. Dr. Hope devotes a large part of his "observations" in questioning Dr. Reece's remarks on the alleged influence of the small-pox hospitals in disseminating the disease, otherwise known as the theory of aerial convection, and says that if Dr. Reece's assertions are well founded the hospital for small-pox erected upon a site carefully selected for the purpose and approved by the Local Government Board, after full and complete inquiries by the Board's experienced inspectors, must be closed as a public danger Dr. Hope challenges Dr. Reece's findings and questions the statements and diagrams by which the theory of aerial convection was supported with reference to the small-pox hospitals of the city. One of Dr. Hope's strongest arguments against this theory lies in the fact that the invasion by small-pox of houses near to the Fazakerley hospital was least when the hospital had most patients. Dr. Hope also emphasises the fact that no hospital had so many surrounding cases of small-pox as one which itself never received a small-pox patient. In reference to Dr. Reece's remarks on p. 9 of his report, stating that "the generally accepted and, so far as I am aware, the only completely satisfactory explanation of the peculiarities of small-pox incidence around hospitals receiving acute cases of the disease is dissemination of infection by aerial convection," Dr. Hope replies that "it must at once be pointed out that the statement that the theory is generally accepted is without justification. The theory is not generally accepted by experts; it is not generally accepted by medical officers of health, and it has been rejected by the High Courts of Justice both in Ireland and England when the theory had been put forward to restrain the use of certain sites for small-pox hospitals." Dr. Hope concludes his "observations" by saying that "neither the Local Government Board nor the port sanitary and hospitals committee could assent to the continued use of the Fazakerley hospital if the allegations contained in Dr. Reece's table are to be regarded seriously." "The committee will, of course, appreciate that Dr. Reece's report derives its importance from the official position which he holds, and although it does not appear that the Local Government Board have adopted the report, or have given official acceptance to it, yet no doubt must be allowed to remain as to the views of the Board and the views of the committee in the matter."

Hospital Treatment of Mental Affections.

Mr. John Carswell, who is certifying medical officer in lunacy cases for the Glasgow parish council, has been pointing out that with respect to applications made to the inspector of poor on behalf of persons supposed to be insane a sorting-out process is necessary in the interests both of the public and of the patients. This can only be done by two methods: first, by a careful medical examination of each case; and, secondly, by provision of a special hospital for the care of the early and transient mental cases. There must necessarily be a considerable proportion of cases presenting mental symptoms which do not require asylum care. He strongly objects to the term "observation wards" as applied to mental hospitals. It leads to the idea that patients are sent there for the purpose of diagnosis, which is not the case. The diagnosis has to be made, if possible, before the patient arrives there. In the Glasgow Hospital the period of residence is limited to six weeks, at the end of which time the patient must be discharged or be certified for the asylum, boarded out, or otherwise disposed of under the lunacy statutes. The patient has perfect freedom of action and there is no power of detention. The hospital is in the midst of a busy district but that causes no difficulty as regards the efficient care and medical treatment of the patients and a certain amount of open-air exercise can be secured. Moreover, the wards are well ventilated and have abundance of light. The average period of residence is about four weeks. Out of 1027 cases reported to the inspector of poor as lunatics 449 were certified insane and were removed directly to the asylum. Of those treated in the mental hospital there were afterwards certified insane and removed to an asylum 134. There were treated in the hospital in addition to those enumerated as having been transferred to the asylum 338. Of these, 213 were discharged recovered, 95 were discharged relieved—i.e., sufficiently well to be sent home or so far recovered from the mental condition as to be cared for in the ordinary wards of a hospital—and 30 had died. There were otherwise disposed of as not certifiable, treated at home, &c., 76. The general result is that of 1027 cases 583 were removed to asylums and 414 were disposed of without recourse to asylum care. The figures seem to justify the general proposition that in a population such as that of Glasgow there is a considerable number of patients who are suitable for treatment in a mental hospital and who could therefore be spared the stigma of being sent to an asylum.

Munificent Gift to Glasgow.

Glasgow has profited much by the gifts of many of her public-spirited citizens and the last possession which she has acquired in that way is by no means her least valuable one. Mr. A. Cameron Corbett, M.P., has notified the Lord Provost that he has agreed to purchase a part of Ardkingloss estate with a view to handing it over to the corporation of Glasgow. The extent of the land in question is 9000 acres and the estate is most exquisitely situated between Loch Long and Loch Goil. As Mr. Corbett says in his letter, his object is "to preserve a grand and rugged region for the best use of those who love the freedom of the mountains and wild natural beauty." In the deed of conveyance a clause is inserted prohibiting the sale of alcoholic liquor and Mr. Corbett suggests that nothing should be done which would mar the naturalness of such scenery. Such a gift is unique and it seems almost unnecessary to descant upon the generosity which prompted it. The corporation has not yet seriously approached the problem of what to do with its new estate but the suggestions put forward by correspondents in the newspapers are legion. Glasgow has hitherto done well in its efforts to provide facilities for those of its citizens who suffer from pulmonary tuberculosis. The work carried on at Bellefield Sanatorium has been largely successful but unfortunately the accommodation there is limited and many patients suitable for treatment are constantly waiting for admission. That this should be so is distinctly unfortunate in the case of a disease in which it is recognised that to obtain the most successful results treatment should be commenced as soon as the disease makes itself manifest. It has been suggested for some time that it would be an advantage to establish a subsidiary sanatorium in the form of a consumptive camp, but one of the difficulties has been to secure a suitable site for such an enterprise. Surely in this large tract of land so generously placed in the hands of the corporation a nook will be found suitable for the establishment of such an institution in a situation where its presence will not interfere with any other plans which may be carried out in order to enable the citizens to take the best advantage of their new possession.

"Tuberculosis and a Simple Life": Lecture by Sir James Grant.

Sir James Grant, M.D., ex-President of the Canadian Association for the Prevention of Tuberculosis, delivered a very interesting lecture in the Young Men's Christian Association Hall, Aberdeen, on August 10th on Tuberculosis and a Simple Life. Dr. J. C. Ogilvie Will presided over a large attendance. Sir James Grant said he was not there as a foreigner but as a Scotchman born and educated in that country. He had merely come from Canada, endorsed by Lord Strathcona, to offer a few observations upon tuberculosis and a simple life, to compare notes with the leading authorities in this country, and to see what could be accomplished by exchange of ideas on those points. After referring to the work of the Canadian Association for the Prevention of Tuberculosis, he said that in mastering or controlling this disease it was absolutely necessary that there should be thorough organisation. Three specific objects were: first, educational; second, preventive: and third, curative. In an educational way a great work was being done by lectures. Then the dissemination of literature was giving people information. With regard to preventive measures, a by-law had been recently passed in Ottawa making it an act for which an individual would be punished—in fact he might be put in prison—if found expectorating in the streets, or on the railways, or in the churches. As regarded curative measures, he said if there was any subject that concerned the welfare of the community it was this matter of the treatment of tuberculosis. They knew perfectly well that sanatoriums were being discussed and erected almost all over the world at the present time. He did not approve of large sanatoriums. Was it to be supposed for one moment that a large number of people huddled together had the same prospect of recovery as by the modern treatment which was going on to-day in the tent and the home? If anyone in the country developed this disease all he had to do was to put up a small tent, fit it up with a bed, a stove, and culinary apparatus, and get the fresh air and modern attention. The house where a consumptive case had been ought to be purified thoroughly and when there was a consumptive patient in the house the health authorities should be notified. He thought a proprietor should be fined if he allowed a second inmate into a house where a consumptive had resided until it was purified thoroughly. The reason why so many took the disease was that their vitality was lowered. If the simpler life was not followed there was danger of a lowered vitality and there would be promoted very readily that condition of the system which would enable the bacillus to settle down and generate tuberculosis. He believed that all schools should be examined by medical experts. The whole question of the treatment of this disease required to be taken into serious consideration by the authorities. Dealing with the question of food and alcohol, he said as regarded food that there was no substance in the whole list of articles of diet that could surpass oatmeal. With reference to the drink problem he was pleased to know that at the present time a marvellous change had been coming over the minds of the people of the world in regard to this extremely important subject. The subject had been carefully, solidly, and substantially investigated. Every day it was growing more popular not to use alcoholic liquors. The lecturer then referred to an interesting visit which he paid to Balmoral and said that he had been thoroughly impressed with the remarkable evidence in all the surroundings of Balmoral of a simple life that contributed in no small degree to lengthen the years which enabled Her Majesty the late Queen Victoria, as woman and sovereign, to influence for good all movements of her time, as if by a unique magnetic power, transmitted to all parts of her empire, throughout which "she made herself understood, beloved, and revered." Dr. Ogilvie Will moved a vote of thanks to Sir James Grant for his excellent address. The subject was one of extreme interest to everyone, to the highest as well as to the lowest in the land. King Edward himself had initiated a home for the treatment of consumption. A great deal had been said as to the establishment of homes for the treatment of tuberculosis amongst the working people. He had always had his doubts as to the expediency of this being carried out on account of the great expense and the impossibility of treating any large number. He did not think that it had been yet proved that sanatorium treatment was the best possible method and he was not sure that Sir James Grant was not advocating the right thing when he suggested treatment of a simple character. He had had reason to raise his voice against that disgusting habit of spitting which went on so largely in Aberdeen. One point was known as the "spitting corner"—beside the Queen's statue—where the loafers seemed to have nothing else to do but to amuse themselves by expectorating. He was glad to see that in the tramway cars there were notices requesting people not to indulge in this filthy habit. He was sorry to say, however, that the rule was not always observed and when on several occasions he found fault with people they seemed to think that he was taking a great liberty indeed.

(FROM OUR OWN CORRESPONDENTS.)

The Death of Mr. John Auterson, L.R.C.P. Edin.

AT an inquest held on August 8th in Cookstown in reference to the sad death by accident of Mr. John Auterson, who had for many years been a practitioner in that town, evidence was given as to the unprotected condition of the road over which he with his vehicle and horse were projected 15 feet. One witness said that the road was unprotected for a long distance in both county Tyrone and in county Derry and was very dangerous. Several accidents have occurred in a similar way on the road, some of them, as a witness testified, resulting fatally. Mr. R. Burgess, J.P., who attended the deceased, said that the road was a disgrace to modern civilisation. The jury returned a verdict in accordance with the medical evidence (shock to the sympathetic system followed by peritonitis), adding a rider in which they drew attention to the dangerous state of this road which is the leading highway from Coagh to Cookstown and on which there is great traffic. The coroner is sending copies of the verdict and rider to the county officials of Derry and Tyrone and to the rural and county councillors concerned. The coroner, the medical witness, and the jury having expressed their sincere sympathy with the friends of the late Mr. Auterson, a brother-in-law of the deceased feelingly replied.

Typhus Fever in Donegal.

An alarming outbreak of typhus fever has occurred in Innishowen, a district of co. Donegal. It is believed that the contagion was brought into the country in second-hand clothes, packed in Glasgow and sold at local fairs. Nine families in Effeshmore, a mountainous district in Clonmany parish, have been attacked and already there has been one death. Dr. B. MacCarthy (medical inspector of the Local Government Board) and the district medical officers are making every effort to stamp out the epidemic. The "contacts" have all been isolated.

A Medical Officer's Holiday.

A curious situation has arisen in Lurgan. It appears that Mr. Hugh Reid, dispensary medical officer of Lurgan No. 2 district, had been granted by the guardians a month's leave of absence on the condition that his substitute would accept 3 guineas weekly, but as he has been unable to find any local locum-tenent who will act at this figure, the chairman announced that if Mr. Reid could find no medical man to act for him at 3 guineas per week he must do without his holiday.

Smiley Cottage Hospital, Larne.

At the second annual meeting of the trustees and consultative committee of this hospital held in Larne on August 11th it was reported that 54 in-patients (and a few out-patients) had been treated. Of the interne cases 30 were medical and 24 were surgical; there were 15 operations. Admirable work is being done in this most useful institution for which the people of Larne and neighbourhood have to thank Sir Hugh Smiley and his generous wife.

Royal Victoria Hospital, Belfast.

Through the kindness of the board of management of the Royal Victoria Hospital the superintendents of the Hospital Saturday collection were entertained on August 12th and were given an opportunity of inspecting the hospital and its working which was much appreciated by the numerous guests who were very hospitably treated.

Belfast District Lunatic Asylum.

At a meeting of the asylum committee held on August 14th it was reported that there were at present on the asylum register a total of 1108 inmates—504 males and 604 females. During the five years ending December, 1904, there were 509 cases received into the asylum from the workhouse and so far this year there had been 53 admissions. Some improved provision will have to be made for the idiots and imbeciles, as neither the workhouse nor the asylum is the proper place for such cases.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Relations between Albuminuria and Diabetes.

AT a meeting of the Academy of Medicine held on July 25th M. Lancereaux said that in his opinion it was an error to suppose that the passage of sugar through the kidney was the cause of the albuminuria which was found in diabetes, because albuminuria was unusual in pancreatic diabetes in which the amount of sugar varied between 500 and 1100 grammes in 24 hours, whereas it was relatively frequent in fatty or arthritic diabetes in which the amount of sugar seldom exceeded 100 grammes. There were three pathogenic conditions which might give rise to albuminuria in diabetes. One was an intercurrent disease, especially tuberculosis. The urine was in that case high-coloured, turbid, and scanty; its specific gravity was increased and it was loaded with flocculent albumin and tube casts; the kidney lesion was epithelial nephritis, quite independent of the diabetes and connected with the general disease. The second of the three conditions above mentioned was arterio-sclerosis with consecutive atrophy of the kidneys. The urine was of low specific gravity, transparent, pale, and abundant; the albuminous precipitate was small in quantity; the kidney lesion was arterial nephritis, which, as well as the diabetes, was of arthritic origin; uræmia was of frequent occurrence. In the last of the three conditions there was neither any intercurrent disease nor arterio-sclerosis. The urine was almost normal in quantity, specific gravity, and colour, and it contained neither tube casts nor leucocytes; the albuminuria was generally abundant and was increased by mental excitement and overwork, but the patient's general health was fairly good and anæmia was rare. This third form deserved to be called albuminous diabetes on account of its constant association with glycosuria, and in accordance with the celebrated experiment of Claude Bernard it ought to be attributed to a disorder of the bulbar innervation.

Præcordial Massage in Heart Disease.

At the same meeting of the Academy of Medicine M. Cautru read an interesting paper on the Utility of Massage of the Cardiac Region in Heart Disease. Such massage had a decided effect on the arterial tension, on the pulse, and on the cardiac dulness. In exaggerated tension he used massage to reduce it and in low tension he used massage to increase it; massage was, in fact. capable of regulating arterial tension. The desired result was generally obtained in from five to ten minutes and at first it lasted for several hours but after successive applications of the treatment, varying from ten to 20 repetitions, the effect became permanent. The particular kind of massage to be used was determined by the blood pressure. In patients with diminished blood pressure and quick pulse massage reduced the frequency of the pulse and increased its amplitude, as was shown by sphygmograph tracings. Furthermore, under the influence of massage the area of cardiac dulness was notably diminished—both the absolute dulness corresponding to the portion of the heart which was in contact with the thoracic wall and the relative dulness due to the interposition of the margin of the lungs. When, however, the pericardium was adherent the absolute dulness remained invariable, a sign which might be useful in the diagnosis of such cases.

Operations for Cancer of the Stomach.

At the same meeting of the Academy of Medicine

M. Poncet read a paper on the Treatment of Cancer of the Stomach by pylorectomy combined with more or less extensive gastrectomy. He said that of 12 such operations six had been successful and he concluded that this operation was in every way preferable to gastro-enterostomy, the latter being at the most only palliative. In conclusion, M. Poncet remarked on the necessity for operating at an early stage of the disease and on the advantages of exploratory laparotomy in doubtful cases.

The Treatment of Phlebitis.

At a meeting of the Société de l'Internat des Hôpitaux de Paris, held on July 27th, M. Vaquez expressed disapproval of the old-fashioned views which encouraged prolonged immobilisation of limbs affected with phlebitis. He recommended movement of such limbs at a period which varied according as the phlebitis belonged to one or the other of its two varieties. In phlegmasia alba dolens and phlebitis obliterans of the large veins he deprecated the use of splints (*gouttières*) which increased the pain and he recommended immobilisation in cotton-wool (*pansement ouaté*), the leg being held in position by tapes fixed to the mattress; he further recommended the use of a bedstead with adjustable fittings and acknowledged that no precise time could be assigned for the duration of the immobilisation, although in the absence of fever about three weeks might be sufficient for the establishment of œdema and pain in the course of the vein, symptoms which were indispensable preliminaries to mobilisation. The second variety of phlebitis, or subacute venous septicæmia, arose in ordinary varicose veins as a result either of a blow or of local infection from an abrasion of the skin. M. Vaquez said that the infection did not always remain localised and might spread extensively along the veins. The preventive treatment consisted in massage, gymnastic exercises, support by means of stockings, and avoidance of mechanical injuries such as blows or wounds of the skin. If subacute septicæmia declared itself complete immobility ought to be maintained for about three weeks, followed by massage not of the phlebitis but of the immobilised joints and of the muscles which were atrophied by disuse. M. Vaquez said that septic phlebitis even when occurring at a low level always required high removal of the veins. He also recommended hydrotherapeutic measures.

Anæsthesia produced by the Combined Use of Scopolamine-Morphine and Chloroform.

M. Walther has recently advocated the production of anæsthesia by the combined action of scopolamine-morphine and chloroform and M. Monod has employed the method in five cases. In four of these the result was quite satisfactory but not so with the fifth patient who was a female. The injection of scopolamine-morphine having been given, chloroform was administered two hours afterwards and M. Monod performed cholecystostomy; 20 minutes after the chloroform was discontinued she was seized with syncope and artificial respiration had to be maintained for more than half an hour. Injections of ether and caffeine were also given. After 20 minutes of apparent death the pulse reappeared and she soon regained consciousness. M. Monod did not think that the mishap could be attributed to the morphine because the patient had already received injections of morphine without any abnormal manifestation. He described the case at a meeting of the Surgical Society held on July 26th.

Surgical Treatment of Facial Neuralgia.

At a meeting of the Surgical Society held on July 27th M. Delbet described three cases in which operations had been performed for the relief of facial neuralgia. In one of the patients he first resected the supra-orbital and infra-orbital nerves but as the neuralgia continued he removed the Gasserian ganglion and the patient remained well for eight months, after which the pain returned. In August, 1902, M. Delbet resected the superior cervical ganglion of the sympathetic. For the first 12 days there was no definite result but afterwards there was an improvement, although not such as to render further treatment unnecessary and the patient was at the present time receiving radiotherapy from M. Béclère. In the two other cases also treated by the same method there was a similar improvement but not complete recovery. Considering that resection of the supra-orbital and infra-orbital nerves was ineffectual while the removal of the Gasserian ganglion was a serious operation and often untrustworthy, M. Delbet concluded that excision of the sympathetic ganglion was preferable because it sometimes yielded successful results.

Paris Milk-supply.

A paper on the Paris milk-supply read by Dr. Henri de Rothschild at a recent meeting of the Société Scientifique d'Hygiène Alimentaire ought to attract the attention of the public authorities. From his observations and analyses of the milk sold in the 20 districts (*arrondissements*) into which the city is divided it appeared that only 22 per cent. of the samples contained a normal amount of fat, the remainder being impoverished. The proportion of inferior quality was 91 per cent. for the milk retailed at 20 centimes per litre (2½d. a quart) and 75 per cent. for the milk retailed at 26 or 30 centimes per litre (3½d. a quart).

Chloride-free Diet in Heart Disease.

At a meeting of the Société Médicale des Hôpitaux held on July 28th M. Vaquez and M. Digne described observations which they had made on the effects of limiting as much as possible the chlorides in the diet of patients suffering from heart disease. They have obtained proofs, on the one hand, that there was a constant retention of chlorides during the continuance of well-marked cardiac symptoms; and, on the other hand, that the minor phenomena, such as nocturnal dyspnœa, transient œdema, and œdematous bronchitis, which preceded urgent cardiac symptoms have a similar origin. Conversely, these cardiac symptoms, whether slight or severe, did not pass off without copious excretion of urinary chlorides (*polyurie chlorurique*). Mere rest in bed with the use of a chloride-free diet would sometimes be sufficient to bring about recovery. A chloride-free diet also assisted the action of diuretics in such cases. In mitral and aortic disease with low arterial tension a chloride-free diet and preparations of digitalis were essential, followed by a prolonged use of theobromine. In mitral and aortic disease with hypertension, conditions which were usually accompanied by renal sclerosis, the most trustworthy treatment consisted in the use of theobromine together with the administration of small doses of digitalis at definite intervals. The "dechloruration" necessary during treatment by digitalis must sometimes be replaced by "hypochloruration" (*régime hypochloruré*). In heart disease a dietary containing very little chloride was in every way desirable, even when the patient felt comparatively well. On the slightest appearance of cardiac symptoms it was necessary as a precaution to prescribe digitalis combined with "dechloruration" lasting for three four days, followed for a week by the administration of one and a half or two grammes of theobromine and a dietary containing very little chloride. When the symptoms were urgent the use of chlorides ought to be regulated in accordance with the results of investigations as to the capacity of the organism for chlorides. Systematic experiments and analyses, combined with a dietary of uniform hydrating and calorific power (*alimentation isohydrique et isothermique*) as described by M. Widal and daily weighing of the patient, would show how much chloride could be taken without danger.

Involuntary Movements of the Fingers in Tabes Dorsalis.

At the fifteenth congress of French-speaking alienists and neurologists held at Rennes from August 1st to 7th M. Sabrazès said that in tabes dorsalis it was not unusual for the fingers to make involuntary movements of adduction, abduction, opposition, and rubbing against one another. This often happened with the forefinger and thumb, which might work like a pair of forceps, especially when the person was speaking. Investigation of the early history of this condition showed that it was preceded by an affection of the hands characterised by awkwardness and loss of sensibility; there was also in the fingers a feeling of numbness which caused the patient to rub them against one another for the purpose of restoring sensibility, thereby manifesting a sort of motor reaction against the feeling of numbness. In other cases these movements corresponded to those executed by the patients in the course of their occupation, such as the manipulation of cloth by a tailoress or the winding of tow on a reel. These involuntary movements were annoying to the patients who endeavoured to disguise them in various ways. Since the attention of M. Sabrazès had been directed to the subject he had observed five cases and had compared the movements with those occurring in tic. Their frequency in tabes dorsalis was of some importance as a symptom.

The Treatment of Incontinence of Urine.

At the Congress of the French Association for the

Advancement of Science, which was held from August 3rd to 10th, M. Ardouin said that he had used Sicard's method of epidural injections in the treatment of 22 cases of incontinence of urine arising from various causes. He adopted Cathelin's procedure of injecting artificial physiological serum in doses varying from 10 to 30 cubic centimetres. He has never observed untoward results, even of a trivial kind. During the injection some patients experienced sensations of pain or weakness in the legs, the back, or even the nape of the neck. The results were very encouraging, as 16 patients recovered and four were improved, while the remaining two showed no change.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Heart Disease and Cycling.

As already reported in these columns,[1] the military authorities have found that there is a considerable increase of cardiac diseases in the army as well as among the conscripts. A special commission appointed to inquire into the matter came to the conclusion that various excesses in which young men indulge, together with the prevalence of influenza, may have contributed to the spread of cardiac troubles. Dr Beyer, a military surgeon, writing to the *Münchener Medicinische Wochenschrift*, has expressed the opinion that a connexion exists between heart disease and cycling. He has examined the conscripts of two army corps, of whom 233 and 293 proved to be suffering from heart diseases. 41 and 110, being respectively 17·6 and 37·5 per cent., of the sufferers were stated to be cyclists and it is remarkable that the cardiac troubles which are most commonly found in cyclists—namely, dilatation and cardiac irritability—were especially frequent among the conscripts. It seemed to be proved that cyclists, especially those following sedentary occupations, such as clerks, school teachers, shopmen, &c., were liable to heart disease, because they cycled long distances on Sundays without having sufficient practice during the rest of the week. Another class consisted of working men who in the evening cycled home from their employment after a day spent in fatiguing exertion. All these people overstrained their hearts by cycling. Cases where soldiers contracted heart disease by cycling in the service were rather rare, because the men selected for that duty were all of strong constitution, were previously examined by an army medical officer, and were kept in regular practice.

The German National Beverage.

Temperance principles are obviously making substantial progress even in quarters where it might be least expected. According to recently published statistics the consumption of beer is steadily decreasing in the city of Munich so justly famous throughout the world for the produce of its breweries. The natives of Munich not long ago neither liked nor recognised any other drink than beer and even children became accustomed to the national beverage at an early age. The result was that fatty heart, arterio-sclerosis, cardiac dilatation, and other diseases of the circulation were "endemic" there, so that the late Professor Oertel of Munich had ample material for his well-known studies on cardiac debility and its treatment. In 1884 the average consumption of beer in Munich was not less than 500 litres per head per annum, but this estimate has decreased to 339 litres in 1903 and 315 litres in 1904 In 1904 the output of the Munich breweries was 3,185,800 hectolitres, of which 1,648,510 were consumed in Munich; in 1903 the output was 3,290,900 hectolitres, of which 1,745,495 were consumed in Munich. The water supplied to the town is of good quality but the average citizen would be astonished at the suggestion that people might drink it habitually. This marvel may, however, come to pass if the consumption of beer continues to fall off at the present rate.

Arhovin.

Arhovin, which is a combination of diphenylamin with thymolic-benzoic acid, has been recently recommended as a specific remedy against gonorrhœa, and Dr. Piorkowski has published in the *Deutsche Medicinische Wochenschrift* the results of researches on the bacteriological relations of the new substance. He states that it has an aromatic smell and an agreeable taste. It is not soluble in water but is soluble in alcohol, ether, and chloroform. It is absorbed by the stomach in from 15 to 20 minutes. Its strong bactericidal action is proved by the destruction of cultures of bacteria. Cultures of staphylococcus and bacterium coli are destroyed within 60 minutes. The destruction of cultures of the gonococcus was even more prompt, these micro-organisms ceasing to grow after a contact of 15 minutes' duration with arhovin. Dr. Piorkowski concludes from his experiments that the substance is likely to be useful both by local administration in gonorrhœa, urethritis, endometritis, and otitis, and also by internal administration in diseases of the urogenital organs, especially in cystitis and pyelitis.

Operative Treatment of Puerperal Septicæmia.

Professor Bumm recently read a paper before the Berlin Medical Society on the Operative Treatment of Puerperal Septicæmia. He said that the results of surgical interference were far from being satisfactory. Neither the use of the curette nor the removal of the uterus was trustworthy, the latter procedure leading to profuse hæmorrhage and moreover leaving the infected stump behind. The same danger was connected with the removal of the ovaries and the tubes. Professor Bumm recommended ligaturing the thrombosed veins, especially in the more chronic cases. He had ligatured the ovarian and hypogastric veins in cases of pyæmia of which only two ended fatally. He usually made a transperitoneal incision as in that way the veins could be reached more easily than by an extraperitoneal method.

August 14th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

The Federative International Congress of Anatomy.

FRANCE has been known to claim chemistry as "a French science" and Italy, with perhaps equal justice, to claim anatomy as an Italian one, but (scientific *chauvinisme* aside) Italian interest in anatomical study rests on a historic basis so solid as amply to account for the strength of her representation at the great congress which begins its session to-day at Geneva. This meeting is the first of its kind and it is to be hoped of a long series, its distinctive feature consisting in its not being an international congress on the traditional lines, assembling in one or other national centre, but the collective gathering together of "anatomical societies" which, after preliminary arrangements inspired by a fraternal spirit truly cosmopolitan, have agreed to hold a *réunion* in common and on neutral ground—and all this with no sacrifice of individuality but with each society under its own president working in harmony with the sister societies in the carrying out of one and the same programme. This coöperation, thanks to its collective or "federative" *motif*, will have an advantage unknown to its merely national predecessors—a larger, more varied, in all respects more comprehensive, representation of the "armamentarium anatomicum," an exposition of all the technical resources of research and instruction, including preparations macro- and micro-scopic, illustrating the whole field of anatomy, human and comparative, in embryology, histology, histo-chemistry, &c., the whole resulting in a maximum of demonstration and a minimum of discursive talk. That this programme is not more ambitious than the powers directing it can justify will at once appear in the enumeration of the promoting societies—the Anatomische Gesellschaft of Germany, founded in 1887; the Anatomical Society of Great Britain and Ireland, dating from the same year; the Association of American Anatomists, now in its eighteenth session; L'Association des Anatomistes, founded in 1899; and the Unione Zoologica Italiana, which originated at Pavia in 1900. Italy, I may add, is fortunate in her representative, Professor Romiti of Pisa, a veteran anatomist and zoologist, who can claim the scholastic paternity of a greater number of pupils holding anatomical chairs and lectureships in Italian seats of learning than any living compatriot. He happens to be president for the year of the Unione Zoologica Italiana and certainly no other Italian could have added to the right due by rotation a stronger claim on scientific and professional grounds to represent her at this first meeting of the Federative International Congress of Anatomy.

---

[1] THE LANCET, August 29th, 1903, p. 637.

The Istituto Antirabbico of Milan.

The Pasteur treatment of hydrophobia can point to few more effective "centres of practice" than the Milanese Antirabic Institute, the report of which for the biennium 1902-03, just out, is as interesting, scientifically and clinically, as any of its predecessors. In 1902 there were 209 persons subjected to the treatment and in the year following 283. Of these, six died at the close of the treatment, two while it was still in progress, and one five days after its termination. The "animali morsicatori" (biting animals) were 492, of which 480 were dogs, eight cats, three oxen, and one man. The institute put in practice three "types of cure," to wit, the normal of 20 days' duration, applied to 437 persons; the "short cure," lasting 15 days and applied to 22 persons; and the "cura intensiva," of 23 days' duration, to which 33 were subjected. (The report incidentally calls attention to the fact that in consequence of experiments made in the institute it was decided, beginning from November, 1903, to modify the traditional method of the Pasteur Institute in Paris—a modification yielding this result: that from that date to April 30th, 1905, no case under treatment at the institute terminated fatally.) As to the sex of the patients 402 were males and 90 females. As regards their age there were 60 cases from one to five years, 105 from six to ten, 79 from 11 to 15, 79 from 16 to 25, 125 from 26 to 50, and 44 from 51 to 80. The "ubicazione" (seat) of the bites was classified as follows: on the face 44 cases with five deaths; at the extremities and exposed parts, 263 with three deaths; and on the non-exposed parts, 183, resulting fatally in one case only. The animals examined at the institute for purposes of experiment and observation were 325. The report proceeds to examine the more "impressionanti" of the fatal cases, well-nigh all them of persons bitten on the face with very extensive lacerations, and records that out of seven the Pasteur treatment proved insufficient in the four gravest cases, but adds that in two of these the "cure," owing to the rapidity with which death supervened, could not develop its action. As to the others, it states that the treatment is efficacious only (1) when the inoculation is not near the nerve centres (which happens when the bites subjected to it are on the face); and (2) when the inoculation of the malady is such as to leave time for the "cure" itself to develop its prophylactic action. A highly interesting section of the report is that with which it concludes, presenting a detailed description of the "protozoa" discovered by Dr. Negri in the nerve centres of hydrophobic animals. This discovery, it claims, admits of a rapid diagnosis being formed, with consequent gain of time and successful results in those cases in which the "Pasteur cure" proved inefficacious because applied too late.

August 6th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Unusual Prolongation of Tabes Dorsalis.

AT a recent meeting of the Society of Practitioners in Vienna Dr. Fuchs showed two patients presenting an unusually long duration of tabes dorsalis. The first was a man, 75 years of age, who, when 16 years old, acquired syphilis. Four years later—namely, 55 years ago, he complained of shooting pain in the legs, *crises gastriques*, and slight disturbance of coördination. 31 years later he sought advice at a hospital on account of atrophy of the optic nerve; he refused to have his pains treated having had them for 30 years. Since then he has remained under medical observation and thus supplies an instance of tabes dorsalis of 55 years' duration. The disease was practically stationary, "prehistoric," as someone said. The other patient, who was a man 60 years of age, began to complain of typical shooting pains 30 years ago without knowing of any specific infection. For the last 22 years he has been under treatment at the hospital, all the symptoms of tabes dorsalis have been present throughout that period, and except variations in the intensity of the pain there is nothing to indicate that the disease is making any progress. These facts seem to show that tabes dorsalis may at least be practically arrested.

Spontaneous Recovery from Progressive Paralysis.

At the same meeting of the above-mentioned society a woman was shown who had a remarkable history. In 1890 she was found to be suffering from typical tabes dorsalis and was treated by massage, hydrotherapy, and iodine. Four years later symptoms of classical progressive paralysis in the expansive form suddenly appeared. Whilst in an asylum a whitlow developed on her right thumb and a deep-seated phlegmon caused sepsis. At the time of operation the phenomena of Argyll-Robertson, Westphal, and Romberg were all present and she had various delusions. When she recovered from the sepsis all the symptoms of paralysis were gone and since that time, 11 years ago, she has remained of sound mind but there is a slow increase in the tabetic symptoms which consist of loss of sensibility of the skin and loss of the tendon reflex in the tendo Achillis. The patient has meanwhile undergone operations for cystitis and pyelonephritis, her left kidney having been extirpated. Septic changes of the blood, perhaps assisted by chronic purulent processes, have therefore been the means of bringing about recovery from paralysis. The different course of psychical and bodily diseases of syphilitic origin is very interesting.

Avulsion of the Deep Flexor Tendon of the Middle Finger.

At a recent monthly meeting of the medical officers of the Vienna garrison Dr. A. Popper showed a man whose hand had been caught in the toothed wheels of an engine. The third phalanx of the right middle finger was torn off and with it there came away the whole tendon of the deep flexor longus for a length of 31 centimetres (12 inches) reckoned from its place of insertion to the seat of injury. The remarkable features of this accident were: (1) the absence of bleeding, which was to be explained by the retraction of the blood-vessels; and (2) the complete restoration of the function of the other fingers although the wound healed by granulation. The time required for healing was five weeks and the only existing sign of the injury was the loss of the phalanx. The treatment consisted in the application of antiseptic dressings and active movements by means of the short flexor, combined with passive movements.

A Nothnagel Scholarship.

The Senate of the University of Vienna has decided to devote £1000 to the purpose of establishing a scholarship in memory of the late Professor Nothnagel. The prize will be awarded to the essay which gives the best answers to medical problems proposed yearly by the Senate. In the case of no essay being deemed worthy of the prize the money will be laid out with a view to encourage original research on diseases of the intestines.

School Hygiene.

The director of the statistical bureau for school affairs has published some very instructive facts concerning the morbidity and mortality of school children. The age period of from 6 to 14 years shows the lowest percentage generally, the susceptibility to pulmonary tuberculosis being also least marked during this period. Tuberculosis was naturally more prevalent among the teaching staff than among the pupils, as the age and occupation of the former gave them an increased susceptibility. The inequality of morbidity and mortality among the children in different districts was due to local variations in connexion with diet, parental care, and promptness of recourse to medical aid. The report therefore recommends systematic medical inspection of schools and an increase in the number of medical officers who ought to be empowered to send children to hospitals if the parents neglect them. In doubtful cases of infectious diseases the child is to be kept away from school. In 1903 there were 97,105 boys and 93,302 girls in the public schools. Of these there was a daily morbidity rate of 3 per cent. for boys and 4½ per cent. for girls. Special classes for feeble-minded and mentally deficient children have been opened in five districts and the German method of teaching deaf-mutes has been universally adopted throughout the Austrian empire.

A Memorial to Professor Finsen.

Funds for the erection of a Finsen memorial have been collected by a committee and a surplus of about £50 remains. It has been decided to use this money to enlarge the laboratory and to increase the surgical appliances in the hospital for lupus.

The Production of Surgical Anæsthesia by Intraspinal Injections.

The intra-dural injection of anæsthetics in the lumbar region for surgical purposes has been carefully studied by Dr. Preindlsberger who described his results at a recent meeting of the Vienna Medical Society. He injected tropacocaine, which is less toxic than beta eucaine or cocaine. The dose was 0·07 gramme, equal to one and a sixth of a grain, in sterilised water, and with the exception of some degree of headache there were no unpleasant after effects. Nausea or collapse was not observed amongst 345 cases operated upon under this form of anæsthesia. The cases included a great variety of laparotomies, amputations, herniotomies, and other surgical operations on the regions below the level of the umbilicus. The analgesia was complete in more than 70 per cent. of the cases, fairly complete in 15 per cent., and inadequate in 15 per cent. In the last category the operations had to be finished under ether or chloroform, of which, however, only a very small quantity (from 20 to 30 drops) was required to control pain. Some of the patients showed a rise of temperature up to 100° or 102° F. for a day or two, after which it soon fell to normal. The injections are made where lumbar puncture is best effected—namely, between the first and second lumbar vertebræ.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Railroad Accidents in the United States.

THE latest accident bulletin issued by the Inter-State Commerce Commission giving the statistics of the railroad accidents which occurred in the United States during the first three months of 1905 shows that during that period 1651 passengers and 2062 employees were injured and 28 passengers and 204 employees were killed as the direct result of railway disasters. Including other causes of injury not immediately due to derailments or collisions the total number of deaths was 909 and of non-fatal casualties 14,937. The total number of accidents was 3108, of which 1787 were collisions. The loss of property to the railway companies alone is estimated at $2,449,248. It is not only the stupendous loss of life and property that gives one pause in considering these figures but also the fact that the number of disasters appears to be increasing from year to year instead of diminishing. This is accounted for by the fact that while the volume of traffic is rapidly growing on all the roads the smaller ones are attempting to carry on their business without double-tracking their lines and installing the expensive signal systems that are essential to the safe operation of the busy modern railroad.

The Warfare against Mosquitoes.

The anti-mosquito propaganda has been carried on with great vigour this year and apparently with effect enough to satisfy the most sceptical. The inhabitants of the New Jersey and Long Island coast towns are reporting an unwonted scarcity of the insects this summer, whereas in previous years the pests have been so troublesome as to render life in these otherwise most attractive summer resorts very uncomfortable. This happy consummation has been effected by diligent destruction of the mosquito larvæ by petroleum, by draining swamps and marshy ground, by thinning the shrubbery in damp localities, by keeping all cisterns, rain-water barrels, &c., screened, and by filling in stagnant pools. During the spring many small streams and creeks were cleaned out and huge quantities of petroleum have been sprayed over the mud-flats at low water. The rural population who at first looked on askance at these measures which seemed to be founded on mere theory have become convinced of their wisdom and are willing to second the efforts of the sanitarians. The insects are unusually scarce, however, even in localities that have not been active in attempts at their extermination and it is supposed that the dryness of the summer so far has rendered conditions less favourable than usual for the development of the larvæ.

A New Hospital Boat for New York.

A craft designed to serve mainly as a hospital transport but in addition equipped for purposes of all-round utility is being built for the city of New York and will soon be completed. Most of the city's contagious disease and detention hospitals are on various neighbouring islands given up to these purposes and the new boat will have eight small wards intended to receive such patients during transit. Each of these is directly accessible from without and they are all constructed of sheet steel so that they may be hermetically closed and fumigated. There will also be a morgue on board and large tanks so that in case of accident to the pipe lines in ordinary use a water-supply may be carried to any of the city's island institutions. The boat will also serve in a less strictly medical capacity, for it is to be provided with powerful pumps intended to be used for fighting fires along the water front and there will be a space left clear on the main deck sufficiently large to accommodate a city fire-engine so that in case of emergency one can be transported to any part of the harbour where it may be needed.

Filtration for New York's Water-supply.

In a recent report just submitted to the mayor the health commissioner of the city of New York urgently recommends the installation of a suitable water filtration plant for the purification of the city's water-supply. Until now the effort has been made to secure safety through the purchase by the municipality of as much territory as possible round about the Croton watershed, which is the source of supply, but it is now recognised that this means of protection is entirely inadequate. It is estimated that a sand filtration plant sufficient for the city's daily consumption of 500,000,000 gallons could be completed within two years at a cost of about $17,000,000.

Typhoid Fever in Chicago.

The customary summer increase in this disease has been more than usually severe and the hospitals contain over a third more cases than a month ago. The data collected show that the proportion of infections contracted outside of the city is steadily rising. Previously to 1900 the proportion of outside cases averaged 20 per cent. but since then it has gradually increased until now it is thought that at least a fourth of the patients acquired the disease in other localities.

To Reform Drunkards.

The grand jury of New Brunswick, New Jersey, has been petitioned to take measures providing that habitual inebriates shall be sent to the State prison for long periods instead of to the county jail. The idea is that in this way they will be given an opportunity to reform and to learn a trade.

Medical Men in Contempt of Court.

The presiding justice of a Washington, District of Columbia, court recently, in addition to a severe rebuke, imposed fines for contempt of court on two physicians who were late in appearing in response to subpœnas. No account was taken of the fact that both were able to show that they could not have presented themselves sooner without neglecting their professional obligations.

A Mother of 25 Children.

A woman who died recently in a Pennsylvania village at the age of 47 years is said to have given birth to 25 children. She was married at 14 and there were only two sets of twins in the 25. 18 children survived and 12 grandchildren are living.

The New United States Pharmacopœia.

The eighth decennial revision of the United States Pharmacopœia has been completed and comes into effect on Sept. 1st, 1905. Among the more notable innovations are several changes in the strengths of tinctures intended to make them conform to the standards recommended at the International Congress on Potent Remedies held at Brussels in 1902. The strength of tincture of aconite has been reduced from 35 per cent. to 10 per cent., and that of tincture of veratrum from 40 per cent. to 10 per cent., while that of tincture of strophanthus has been increased from 5 per cent. to 10 per cent. Several of the more widely used synthetic remedies of definite composition have been admitted and for the first time statements of the average dose of each drug or preparation are appended to the respective descriptions. Numerous changes in terminology have also been made, such, for example, as the coining of the term fluidextractum to replace the older extractum fluidum. In spite of active attempts made by certain spelling "reformers" to curtail such terms, the final *e* is retained in the names of the alkaloids, the halogen compounds and such words as oxide. The number of articles added to the Pharmacopœia is quite large but fortunately it is exceeded by that of the omissions.

The Yellow Fever Situation.

The yellow fever epidemic in New Orleans has not yet been got under control though the morbidity has been greatly restricted by the active efforts of the sanitarians. On August 8th there had been 565 cases of the disease, with

113 deaths, and new cases are being reported at the rate of from 30 to 50 a day. This is a very encouraging showing, as previous epidemics have spread much more rapidly and it is also gratifying to note that very few cases have been discovered outside the city itself. The fact that some of the health boards of the surrounding states were unwilling to trust entirely to the mosquito theory of transmission of the disease in many cases led to the enforcement of the fear-inspired quarantines of the shot-gun type that worked so much injustice in former years. In consequence there were numerous clashes between the health officers of different regions, but at the petition of the citizens of New Orleans the Federal Government has stepped in and the entire situation is now under the direction of the United States marine hospital service, so that uniformity in quarantine regulations is assured. The efforts of the sanitarians in the infected city are based entirely on the assumption that by screening all patients and destroying all breeding places for the mosquitoes communication of the disease is impossible, so that the epidemic may be regarded as a crucial test of the mosquito theory.

August 10th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Bubonic Plague.

BUBONIC plague is still prevalent at Maryborough, Queensland, and there have been seven deaths, the last being that of a nurse at the General Hospital. An influential deputation, representing merchants, shipping companies, and others, waited on the Premier of Queensland to ask that effective measures should be taken to counteract the effect of the plague restrictions imposed by the New South Wales authorities, which were a serious check on Queensland trade, and urged, if other means failed, that an embargo should be placed on all goods from New South Wales. The Premier, in reply, regretted that the deputation had not waited till Dr. J. Ashburton Thompson, the President of the Board of Health of New South Wales, had reported on the subject. He had made representations to the New South Wales Government and also to the Commonwealth Prime Minister, who considered that the matter was one for the Federal Parliament to deal with in a Federal Quarantine Act. The Premier of Queensland declined to put an embargo on merchandise from New South Wales, saying that to protect the trade of one State against that of another by quarantine was improper. During a recent conference between the Prime Minister of the Commonwealth and the Premier of New South Wales the former raised the question of the restrictions imposed by the New South Wales Board of Health against fodder and other produce from Queensland. He regarded the restrictions as an infringement of the Commonwealth Constitution Act. The Premier of New South Wales denied this view and maintained that a State was free to impose restrictions of the most stringent kind to protect the health of a large city, and observed that the restrictions applied equally to New South Wales ports on the north coast. He believed that an amicable settlement would follow the visit of Dr. Thompson to Brisbane.

The Health of Melbourne.

The officer of health of the city of Melbourne, Dr. J. Jamieson, has furnished his annual report to the city council. It showed that during the year reviewed the total deaths in the city numbered 869, being a considerable reduction on the figures for the previous year, which was a period of exceptionally low mortality. For the three years 1901, 1902, and 1903 the deaths numbered respectively 1075, 1012, and 931. For 1904 the mortality was in the proportion of 12·82 per 1000 of the estimated population, which is considered an exceptionally low rate, the proportion in 1903 having been 13·8. The mortality from epidemic diseases during 1904 was slightly higher than in 1903. The number of births registered in the year, exclusive of those in the Women's Hospital, was 1175, considerably below the average of the last few years. Deducting from the total number of deaths under one year those occurring in the same hospital, the number 98 is obtained, giving the remarkably low death-rate of 83·4 per 1000 births. Last year the rate—105 per 1000—was regarded as unprecedentedly low. The infant mortality rate during each of the four periods of five years each, from 1885 to 1904 inclusive, averaged 194, 152, 156, and 110 respectively. The figures show that there has been through the last five years a steady, if not quite uniform, gain in the saving of infant life and thus some compensation has been obtained for the fall in the birth-rate.

The Adulteration of Food in Melbourne.

Appended to the report of the health officer was a return of analyses made by the city analyst. Of 83 samples of milk subjected to analysis, 13 passed the standard of purity, 47 passed the "limit" allowed and 14 were below the limit in percentage of non-fatty solids, one contained fatty solids equal to only 0·32 per cent., and one was deficient by at least 12 and probably 34 per cent. of its fatty solids. Nine samples were found to contain added water in quantities ranging from 3 to 15 per cent.; 23 were artificially coloured, and two contained boric acid. Of 20 samples of eucalyptus oil submitted three only passed the tests of the British Pharmacopœia. Five samples of lime-juice were examined, of which only one was the genuine article. Of the others one was slightly below the limit and another passed it but contained 42 grains of salicylic acid and 8 grains of sulphurous acid to the imperial gallon.

Pulmonary Tuberculosis in Victoria.

At the last meeting of the Board of Public Health of Victoria the chairman (Dr. Norris) drew attention to the death-rate from pulmonary tuberculosis in the State and its variations in different centres. In the Melbourne metropolitan area, where pulmonary tuberculosis was a notifiable disease, the proportion of deaths had fallen between 1889 and 1904 from 20 to a little over 13 per 10,000. In Bendigo it was still over 22 per 10,000 and in Ballarat over 16 per 10,000, the same as in 1899, and the highest in the State except Bendigo. He moved that the section of the Health Act stipulating that cases of pulmonary tuberculosis must be notified should be enforced at Ballarat and Bendigo to enable the local councils to take more preventive measures, especially by disinfecting infected centres. The motion was carried with the addition that the provision of the Act should also apply to Geelong. It may be explained that Bendigo has the reputation of being a suitable climate for consumption and consequently attracts sufferers from the disease who die there. The authorities are taking action to compel medical practitioners to notify pulmonary tuberculosis. At Prahran recently a medical man was fined for not doing so and the Hawthorn council has resolved "that local medical practitioners be informed that unless cases of pulmonary tuberculosis are in future reported in accordance with the provisions of the Health Act prosecution would ensue."

The Asylums for the Insane in Victoria.

The recently appointed inspector-general of the insane for Victoria, Dr. W. E. Jones, has furnished a report on the condition of the asylums in that State. He says that all the institutions are considerably overcrowded and that much of the existing accommodation is of an extremely unsatisfactory character. Dealing with the cost of administration he says that the weekly cost of the patients has only been 11*s.* 7*d.*, nearly half of which is paid in salaries and wages, leaving the very moderate amount of 6*s.* 2*d.* per week to be spent on the patient's food, clothing, medical comforts and necessaries. It appeared that things were being worked in possibly too economical a manner. He recommended that the Ararat gaol ward should be given up, that Yarra Bend, broadly speaking, should be rebuilt from end to end, that the Sunbury Asylum should be considerably increased in size, that various improvements should be made at Kew, that the whole of the male side at Ballarat should be remodelled, and that extensive alterations should be made at Ararat and Beechworth. Attached to the report is a table of overcrowding, showing that there are 600 patients too many in the asylums. There is also a table of proposed buildings and alterations, involving an estimated expenditure of £245,800. The principal items are £22,000 for building and refitting the receiving house; £54,000 on alterations to Yarra Bend; £21,500 for Kew; £10,400 for a new idiot asylum; £53,000 for Sunbury, including £24,000 for two new infirmary wards and two new epileptic and suicidal wards to accommodate 180 patients; £32,000 for Ballarat, including £10,000 for a new administrative block; £13,000 for Beechworth; and £16,400 for Ararat. Another table shows that Dr. Jones recommends additional appointments involving £4705 in salaries. The Cabinet has considered the report but has not decided what action will be taken. It proposes to set aside £50,000 for asylum needs this year.

A New Wing at the Wentworth Sanatorium.

On June 3rd a new wing was formally opened by the Premier of New South Wales at the Queen Victoria Sanatorium for the treatment of early cases of consumption at Wentworth Falls, New South Wales. The original building, which was opened in 1903, had 20 beds; the additions will give a total of 44 beds, besides eight shelters, and it is estimated that the institution will be capable of treating about 200 patients annually. The cost has been about £22 per annum per bed.

Infectious Diseases Hospital, Melbourne.

Measles is epidemic in Melbourne and suburbs but the infectious diseases hospital will not take in cases of this disease as it provides only for scarlet fever and diphtheria. The Melbourne and other metropolitan hospitals also refuse admission to such cases.—The medical students at the University of Melbourne have written to the committee of the infectious diseases hospital asking for permission to attend the practice of the hospital in their fifth year to observe cases not seen at the other hospitals. The request was referred to the superintendent to make arrangements to meet the desire of the students.

Alleged Manslaughter by a Medical Man; Acquittal.

On June 8th Dr. F. W. Marshall was for the third time tried at the Central Criminal Court, Sydney, on a charge of manslaughter and this time the jury returned a verdict of not guilty. On the two previous occasions the jury could not agree. The medical evidence was the same as at the previous trials.

Defective Vision in Mariners.

The Court of Marine Inquiry of New South Wales found that a recent collision at sea was caused by the defective vision of the master of one of the vessels.

July 4th.

Obituary.

JOHN WILLIAM OGLE, M.D. OXON., F.R.C.P. LOND.,

CONSULTING PHYSICIAN TO ST. GEORGE'S HOSPITAL.

IN our last issue we announced the death of Dr. John William Ogle which occurred on August 8th at the Vicarage, Highgate, the residence of his son. Dr. Ogle was a member of a family well known both at Oxford and at St. George's Hospital, at which institution two other members of the same family were pupils—viz., Dr. William Ogle of Derby, whose death occurred a few weeks ago, and Dr. William Ogle of the Registrar-General's office, while of the younger generation Dr. Cyril Ogle, a son of Dr. John Ogle, is now physician to the hospital. John Ogle was born in the year 1824 and graduated at Trinity College, Oxford. He joined the school of St. George's Hospital in the year 1847, together with Mr. Timothy Holmes, at a time when Prescott Hewett was lecturer in anatomy and Henry Gray was demonstrator of the same subject. The latter was the most active teacher among an exceptionally diligent and intelligent circle of students, among the members of whom were J. H. Bridges and Pearson, then fresh from Oriel and soon to distinguish himself in Australian political life. Ogle was an ardent student of anatomy. He lived for a time in Mr. Hewett's house and was soon appointed to demonstrate anatomy in the school, being also for some time curator of the museum together with Gray. For a time he lectured on anatomy and on Gray's sudden death he remained in charge of the pathological department. During these early years at St. George's Ogle commenced a career which was soon to conduct him to eminence both as a physician and as a hospital teacher. He took the degree of M.D. in 1857 and became a Fellow of the Royal College of Physicians of London in 1855. In 1866 he joined Mr. Timothy Holmes as co-editor of the *St. George's Hospital Reports*, a series which extended to ten volumes, Ogle being co-editor of the first seven of these volumes, but in the year 1874 his place was taken by Dr. W. H. Dickinson. Apart from the intrinsic value of its contents the series of Hospital Reports did no little service in keeping up the *esprit de corps* of the school and in securing the efficiency of the junior departments of the hospital—viz., the registers and the museum—so ably organised and supervised by such men as Edgar Hawkins and Prescott Hewett. Dr. Ogle was a man of wide sympathies in matters outside the medical profession. He was a deeply religious man of the school of the early Tractarians or High Churchmen, with whose leading members, such as Sir R. Inglis, Mr. Gladstone, Keble, and others, he had intimate relations. The last time probably that he attended any gathering at St. George's was when Dr. Temple, Archbishop of Canterbury, an old Oxford friend of his, gave the prizes to the successful students. The late Dean of St. Paul's, Dr. Church, was also one of his sympathising friends. He was also interested in antiquarian matters and was a Fellow of the Society of Antiquaries, and in 1884 he was elected to "Nobody's Club" on the nomination of Mr. G. Richmond, R.A., and Dean Church.

Dr. Ogle soon attained a large practice. He was happily married and but for somewhat infirm health would have seemed to have all that was necessary for felicity. He was elected on to the staff of the hospital as assistant physician in March, 1857, on Dr. Wilson's retirement, and became full physician in May, 1866. But the strain of private and hospital practice proved too much for him and he fell into a condition of melancholia, from which he suffered for many months, and from which he recovered in a very singular manner, for he had somehow contracted typhoid fever, for which his friend Dr. (afterwards Sir) W. Jenner attended him and which seriously threatened his life; but when the danger had left him his mind quite recovered its tone and he remained fit for all the purposes of active life. But he had felt it prudent to resign his hospital appointment in 1876 and was elected consulting physician in May, 1877. For some years Dr. Ogle continued in private practice, but a few years ago he found it time to spare himself such anxiety and labour and went to live at Highgate. His friends were glad to learn that this change had been entirely for his happiness and that he continued to enjoy life in spite of failing strength and the increasing infirmities of old age. Finally, he lost partly the power of articulation, then unconsciousness supervened, and he passed away peacefully and without suffering on August 8th.

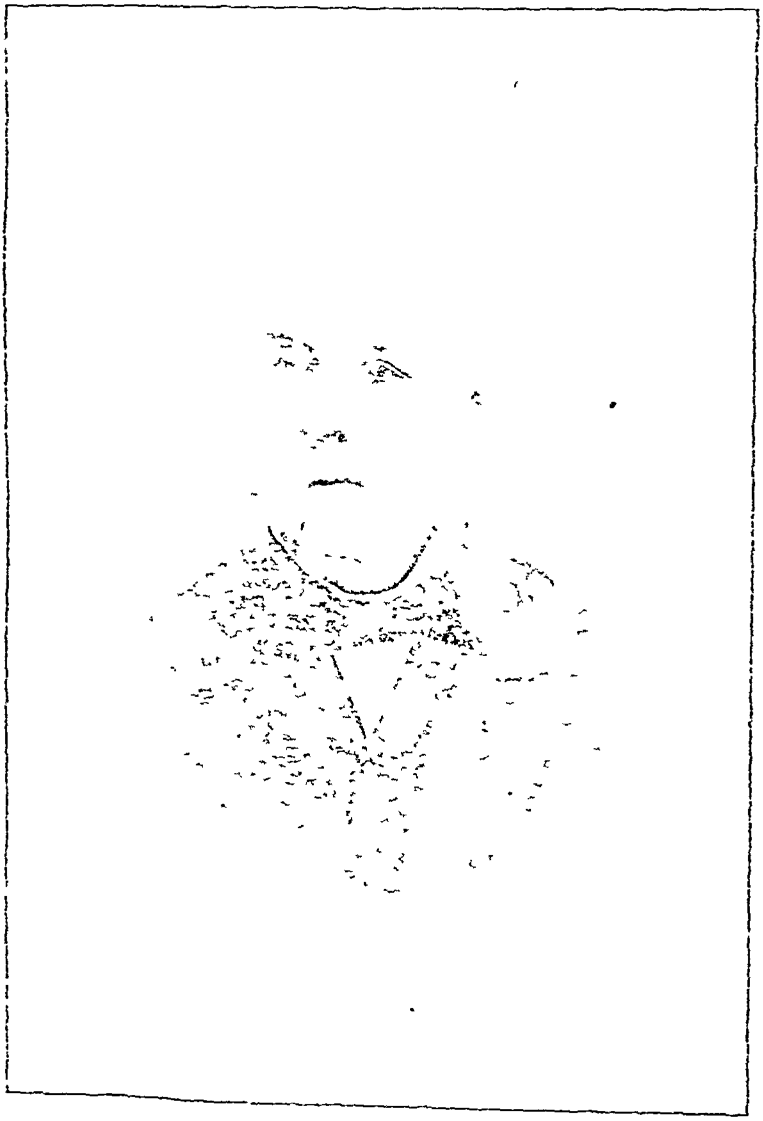
Such is a very imperfect record of a life the innocence and virtue of which made everyone who knew him his friend. Of no one could it be more truly said, "He was good if ever good man lived." Ruder health and a more combative temper might have pushed him further forward in the race of life but for this he had no ambition. He had done good service to St. George's and had been faithful in the higher service to which he devoted himself and that was enough for him. "Cui Pudor et Justitia soror, incorrupta Fides nudaque Veritas. Quando ullum inveniet parem?"

WILLIAM FRAZER, M.D. T.C.D., M.R.C.P., L.R.C.S. IREL.

Dr. William Frazer of Bournemouth died at his residence in Madeira-road on July 26th, after an illness of about three weeks' duration. He was the eldest son of the late Dr. William Frazer of Harcourt-street, Dublin, and received his professional education in the medical school of Trinity College in that city, graduating as M.B. in 1873 and taking the diploma of L.R.C.S. Irel. in the same year. He proceeded to the degree of M.D. in 1878 and was admitted a Member of the Royal College of Physicians of Ireland in 1887. After becoming qualified he was for a time in the service of the Peninsular and Oriental Steamship Company and held the appointment of resident medical officer in the Royal National Hospital for Consumption and Diseases of the Chest at Ventnor in the Isle of Wight. In 1878 he went from Ventnor to Bournemouth, where he became physician to the National Sanatorium for Consumption and Diseases of the Chest, to the Bournemouth Royal Victoria Hospital, and to St. Mary's Home for Invalid Ladies. Dr. Frazer was for several years one of the sidesmen at Holy Trinity Church. He had an extensive private practice and will be deeply mourned by a large circle of friends and patients. He has left a widow, a son, and a daughter.

EDWARD THOMAS BLAKE, M.D. ABERD., M.R.C.S. ENG.

Dr. Edward Thomas Blake, who died on July 31st, was born at Taunton in 1842, being the fourth son of Dr. James



John William Ogle, M.D. Oxon., F.R.C.P. Lond.

A New Wing at the Wentworth Sanatorium.

On June 3rd a new wing was formally opened by the Premier of New South Wales at the Queen Victoria Sanatorium for the treatment of early cases of consumption at Wentworth Falls, New South Wales. The original building, which was opened in 1903, had 20 beds; the additions will give a total of 44 beds, besides eight shelters, and it is estimated that the institution will be capable of treating about 200 patients annually. The cost has been about £22 per annum per bed.

Infectious Diseases Hospital, Melbourne.

Measles is epidemic in Melbourne and suburbs but the infectious diseases hospital will not take in cases of this disease as it provides only for scarlet fever and diphtheria. The Melbourne and other metropolitan hospitals also refuse admission to such cases.—The medical students at the University of Melbourne have written to the committee of the infectious diseases hospital asking for permission to attend the practice of the hospital in their fifth year to observe cases not seen at the other hospitals. The request was referred to the superintendent to make arrangements to meet the desire of the students.

Alleged Manslaughter by a Medical Man; Acquittal.

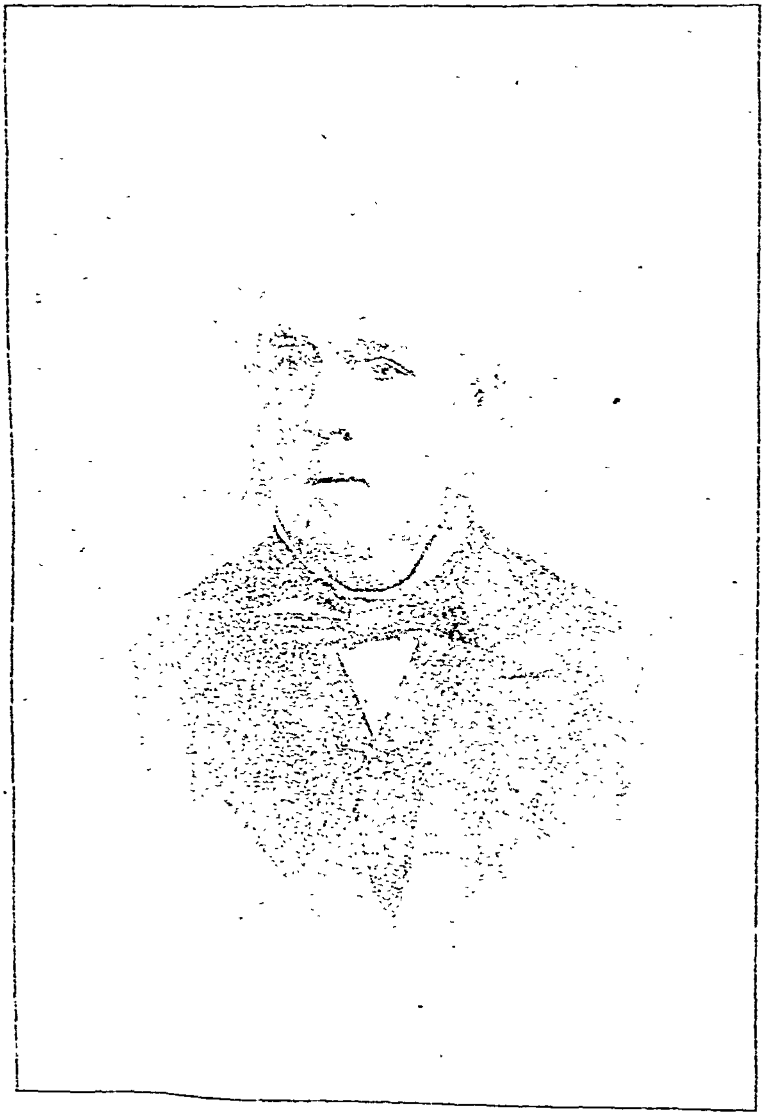
He had done good service to St. George's and had been faithful in the higher service to which he devoted himself and that was enough for him. "Cui Pudor et Justitia soror, incorrupta Fides nudaque Veritas. Quando ullum inveniet parem?"

WILLIAM FRAZER, M.D. T.C.D., M.R.C.P., L.R.C.S. IREL.

Dr. William Frazer of Bournemouth died at his residence in Madeira-road on July 26th, after an illness of about three weeks' duration. He was the eldest son of the late Dr. William Frazer of Harcourt-street, Dublin, and received his professional education in the medical school of Trinity College in that city, graduating as M.B. in 1873 and taking the diploma of L.R.C.S. Irel. in the same year. He proceeded to the degree of M.D. in 1878 and was admitted a Member of the Royal College of Physicians of Ireland in 1887. After becoming qualified he was for a time in the service of the Peninsular and Oriental Steamship Company and held the appointment of resident medical officer in the Royal National Hospital for Consumption and Diseases of the Chest at Ventnor in the Isle of Wight. In 1878 he went from Ventnor to Bournemouth, where he became physician to the National Sanatorium for Consumption and Diseases of the Chest, to the Bournemouth Royal Victoria Hospital, and to St. Mary's Home for Invalid Ladies. Dr. Frazer was for several years one of the sidesmen at Holy Trinity Church. He had an extensive private practice and will be deeply mourned by a large circle of friends and patients. He has left a widow, a son, and a daughter.

EDWARD THOMAS BLAKE, M.D. ABERD., M.R.C.S. ENG.

Dr. Edward Thomas Blake, who died on July 31st, was born at Taunton in 1842, being the fourth son of Dr. James



JOHN WILLIAM OGLE. M.D. OXON., F.R.C.P. LOND.

Dore Blake. He was educated at the Independent College, Taunton, and pursued his medical studies at University College, London, becoming a Member of the Royal College of Surgeons of England in 1863 and graduating M.D. at the University of Aberdeen in 1872. He first practised at Wolverhampton and subsequently at Reigate. In 1880 he came to London where he practised largely as a gynæcologist until within a few weeks of his death. Dr. Blake was the author of numerous medical writings and was one of the first in this country to recognise the important part played by sepsis in disease processes; and it was probably because he was somewhat heterodox, especially in the earlier part of his medical career, that he did not receive the ready recognition which the quality of his work and his undoubted talents deserved. His strong point as a physician was treatment and it would be difficult to find anyone more thorough and painstaking in this respect than he was. He was a man of pronounced individuality and of remarkable energy and enthusiasm. His information was encyclopædic and he was a master of detail, which very circumstance perhaps prevented him always from distinguishing the essential from the non-essential. His wide culture, quickness, and versatility made him a brilliant conversationalist, and nothing delighted him more than a long day in the country with a kindred spirit, when he could fully indulge his passion for natural history and folk-lore. He leaves a widow and one son who has already achieved distinction in the world of art.

Medical News.

UNIVERSITY OF LONDON.—At the intermediate examination in medicine held in July the following candidates were successful:—

Alicia Pears Aldous, London (Royal Free Hospital) School of Medicine for Women, Leonard Tilsley Baker, Guy's Hospital, Henry Lewis Barker, St. Mary's Hospital, *Frederick James F. Barrington (scholarship in physiology), University College, Kathleen Baylis, University College, Cardiff; Alfred Bernstein, Victoria University, Lilias Margaret Blackett, London (Royal Free Hospital) School of Medicine for Women, Trevor Laurence Bomford, St. Bartholomew's Hospital, William Francis Bowen, University College, Edward Wrigley Braithwaite, University of Leeds, John Webster Bride, Victoria University, Kate Brown, London (Royal Free Hospital) School of Medicine for Women, Arthur Burrows, London Hospital; Rhoda Hicks Butler, London (Royal Free Hospital) School of Medicine for Women, George Spence Candy, London Hospital, Howard Bernard Carter, Guy's Hospital, Samuel Earle Cathcart, Middlesex Hospital, Walter Chesters, St Mary's Hospital and University College, Cardiff; James Aitken Clark, St. Thomas's Hospital, Cecil Clarke, University College, Bristol; [illegible] ersity College; Stanley [illegible] Ernest Marshall [illegible] spital, London (Royal Fr[illegible] Cox, Westray Cropper, [illegible] John Davis Woodcock Daniels, St. Ma[illegible] William Denning, Guy's Hospital, [illegible] Mary's Hospital, Donald Frederic[illegible] Gladys Margaret C. Dunbar, Londo[illegible] of Medicine for Women, Raymond Charles Viner Edsall, Guy's Hospital, Douglas Gordon Evans, London Hospital, Vera Foley, London (Royal Free Hospital) School of Medicine for Women, Harold Sydney Furness, University College, Eric Leigh Fyffe, St Thomas's Hospital, †Eric Gerald Gauntlett, King's College, *William Gilliatt, Middlesex Hospital, Alexander Edward Gow, St Bartholomew's Hospital, Thomas John Hallinan, Charing Cross Hospital, John Maximilian Hammond St. Bartholomew's Hospital and University College, Bristol, ‡Clement Hoyle Heppenstall, University of Leeds, Susie Eleanor Hill, London (Royal Free Hospital) School of Medicine for Women; Frederick George Hitch, London Hospital, Maurice James Holgate, St. Bartholomew's Hospital, Henry Holroyd, Middlesex Hospital, Charles Reginald Hoskyn, St. Bartholomew's Hospital; Matilda Hunt, London (Royal Free Hospital) School of Medicine for Women, William Johnson, Guy's Hospital, John Edward Lionel Johnston, St Mary's Hospital, Robert Henry Hatten Jolly, Charing Cross Hospital, Arthur Rocyn Jones, University College, Cardiff, Rose Fanny Jordan, London (Royal Free Hospital) School of Medicine for Women, Harold Holmes King, St Bartholomew's Hospital, Elsie Marian Layman, London (Royal Free Hospital) School of Medicine for Women, John Lewis, University College, Cardiff, Edward Leslie Martyn Lobb Guy's Hospital; Dermot Loughlin, London Hospital, Oswald William McSheehy, St. Thomas's Hospital, Robert Vernon G Monckton, St. Bartholomew's Hospital, Emily Helen Morris and Florence Muriel Morris, London (Royal Free Hospital) School of Medicine for Women, Austin Threlfall Nankivell, St. Bartholomew's Hospital; Ernest Edwin T Nuthall, St Thomas's Hospital; Geoffrey Eugene Oates, St Mary's Hospital, John George Owen, University College, Walter Henry Palmer and ‡John Parkinson, London Hospital; Herbert Edward Perkins, Guy's Hospital, William Joseph Petty, University College, Cardiff; Hilda Margaret Pollard, London (Royal Free Hospital) School of Medicine for Women; Dan Arthur Powell and Laura Gertrude Powell, University College, Cardiff, Robert Bernard Price, St. Bartholomew's Hospital; Joseph Francis E. Shirgaokar, King's College and Grant Medical College, Bombay, ‡Latimer James Short (scholarship in pharmacology), University College, Bristol; James Thornton Smalley, Guy's Hospital; George Francis Rawdon Smith, University of Liverpool; St. John Alexander M. Tolhurst and Vincent Townrow, Guy's Hospital; Norman Hamilton Walker, St. Bartholomew's Hospital; Enid Margaret Walters, London (Royal Free Hospital) School of Medicine for Women; †Albert James Walton (scholarship in anatomy), London Hospital; †Charles Henry Shorney Webb, Middlesex Hospital; *Henry Whitehead, Victoria University; Margaret Hannah Wild, B.A., London (Royal Free Hospital) School of Medicine for Women; Herbert George Willis, St. Mary's Hospital; Sophia Margaret V. Witts, London (Royal Free Hospital) School of Medicine for Women; William Wallace Wood, London Hospital; and Arthur Lowndes Yates, St Bartholomew's Hospital.

*Distinguished in Physiology †Distinguished in Anatomy.
‡Distinguished in Pharmacology.

This list, published for the convenience of candidates, is issued subject to its approval by the Senate.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held in August the following candidates passed in the subjects indicated:—

Surgery.—H. J. Aldous (Section II.), King's College Hospital; C. W. S. Boggs (Section II), Leeds; H. A. Browning (Sections I. and II), Cambridge and St. George's Hospital, and G. M. Seagrove (Section II), St. Bartholomew's Hospital.

Medicine—P. D. Addis, University College Hospital; C. W. S. Boggs (Section II), Leeds, J H. Harrison (Section II.), Sheffield; F. J. F. Jones (Section I), Guy's Hospital; E. B. Miles and W. G. O'Malley (Sections I. and II), London Hospital; W. V. Pegler (Section II), Leeds; N. A. Stutterheim (Sections I. and II), Utrecht, and A. Whitby, Dublin.

Forensic Medicine.—E. Moir, Manchester; and N. A. Stutterheim, Utrecht.

Midwifery—E. Moir, Manchester, A. F. Palmer, Middlesex Hospital; and F. C. H Powell, King's College Hospital.

The diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery: H. J. Aldous, C. W. S. Boggs, H. A. Browning, E. B. Miles, and N. A. Stutterheim

DONATIONS AND BEQUESTS.—Mr. John Rotherham has by will bequeathed £1000 to the Coventry and Warwickshire Hospital.—Sir Massey Lopes has given £500 Consols to the funded property of the Royal Eye Infirmary, Plymouth.

MEDICAL MAGISTRATES.—Mr. Bernard Roth, F.R.C.S. Eng., has been appointed a justice of the peace for the county of Middlesex.—Mr. A. Wood, M.B., C M. Edin., has been added to the roll of magistrates for the borough of Southport.

THE interesting series of engraved mezzotint portraits of famous physicians, surgeons, and medical writers formed early in the last century by the well-known antiquarian, T. J. Pettigrew, formerly librarian to the Duke of Sussex, will be sold by Messrs. Knight, Frank, and Rutley at their rooms in Conduit-street, London, W., on August 23rd.

VACANCIES IN RUSSIAN HOSPITALS.—The St. Petersburg authorities are exercised about the shortage of medical men for the town hospitals owing to the requirements for the army. The only capable men for the vacancies are Jews, against whom there are obstacles caused by the regulations. As it is now a purely legal question the town authorities have decided to consult counsel as to whether Jews may be invited to fill the vacancies.

LITERARY INTELLIGENCE.—Messrs. Oliver and Boyd of Edinburgh have in preparation a small volume on "Scottish Sanitary Laws and Principles of Public Health" by Dr. W. J. Brock, medical officer of health of Midlothian. This book is intended for the use of county and borough councillors, medical officers of health, and sanitary inspectors. It will be published next month.—Dr. C. J. Lewis and Mr. J. N. Lewis, Fellow of the Institute of Actuaries, have in the press a work analysing the Scottish births registered in the first year of registration. These are the only birth statistics existing in this country which contain full details as to the duration and fecundity of marriage. M. Kiaer made special reference to the existence of these Scottish statistics in his recent address on the Fecundity of Marriage to the International Statistical Institute. In this work these statistics will be comprehensively dealt with and interesting deductions will be drawn from the results. The book will be published during the autumn by the same publishers.

ROYAL CORNWALL INFIRMARY, TRURO.—The recently issued annual report of this institution states that 476 in-patients were admitted during 1904, against 392 in 1903. The out-patients numbered 1003, compared with 876 in the previous year. The cost per bed was £54 3*s.* 5*d.*, compared with £58 16*s.* in 1903. The report adds that Sir R. Harvey gave £1000 for the endowment of a bed in the women's ward in memory of Lady Harvey. The financial statement showed that the income amounted to £2113 and a favourable balance of £3 remained.

INFECTIOUS DISEASE AND ELEMENTARY SCHOOLS.—On the suggestion of Dr. E. M. Smith, medical officer of health, the York corporation health committee passed the following resolution on July 31st:—

> That this committee having been informed of the discretionary powers now granted to educational authorities by the new Code just issued, with regard to the admission to school of children under the age of five years, hereby express the hope that, in view of the extensive prevalence of infectious diseases in infants' schools in this city during the last few years and on the grounds of the general health of children of tender age, the Education Committee will in future do their utmost to discourage the attendance of children under the age of five years in all the elementary schools in the city.

ATTACK ON A RUSSIAN MEDICAL STAFF.—The *Government Gazette* of Saratov contains an account from the governor of the province of the circumstances of an attack on medical men at Balaschoff on August 3rd, where 2000 people, incensed against the medical staff on account of their having declined to serve in the province, gathered round the hotel in which the medical men were holding a conference. They sang songs and threatened them with lynch law. On the governor's interference the crowd dispersed but when he was about to convoy the medical men, who had taken refuge in the bedrooms and even attics of the hotel, under the protection of Cossacks to the railway station some of the crowd stoned them, the governor himself being wounded on the hand. With great trouble he got his *protégés* clear. After damaging some property the crowd fell upon and beat Dr. Schmeleff and Dr. Nevsoroff whom they found in the street. The report states that the proceedings were unlawful and that the guilty parties will be proceeded against and if the disturbances are repeated they will be repressed with the aid of the soldiers.

PRESENTATIONS TO MEDICAL PRACTITIONERS.—At St. Germans (Cornwall) on August 4th Mr. J. Bedford Kerswill, M.R.C.P. Edin., M.R.C.S. Eng., who is leaving the town after practising in the district for the past 40 years, was presented with a silver two-handled tea tray, Queen Anne pattern, weighing over 130 ounces, and a silver urn to match. The tray was suitably inscribed and the arms of Mr. Kerswill were also engraved. He was also the recipient of an illuminated album containing the names of 500 subscribers. The Earl of St. Germans made the presentation on behalf of the subscribers at a public meeting and amongst others present were the Countess of St. Germans, the Countess of Dartrey, Lady Mary Dawson, the Hon. John Eliot, and Canon Westmacott. —At the Hambrook (Gloucestershire) mission room on August 5th the vicar (the Rev. W. Brooke), on behalf of the members of the Hambrook Women's Sick Club, presented Mr. W. F. B. Eadon, L.R.C.P., L.R.C.S. Edin., with a mahogany revolving book stand having a silver plate suitably inscribed in recognition of his services as lodge surgeon.

Parliamentary Intelligence.

HOUSE OF COMMONS.

WEDNESDAY, AUGUST 9TH.

Royal Commission on Tuberculosis.

Mr. REGINALD LUCAS asked the President of the Local Government Board when it was probable that the work of the Royal Commission on Tuberculosis would be completed and a final report presented.—Mr. GERALD BALFOUR replied: It is not possible to say at present when the final report of the Royal Commission will be issued but I understand that the Commission hopes to make an interim report towards the end of the present year.

Arsenical Poisoning.

Sir CUTHBERT QUILTER asked the President of the Local Gov ment Board whether, with a view to giving effect to the recomme tions of the Royal Commission on Arsenical Poisoning, the arra ments foreshadowed in his predecessor's statement had now effected; whether the special inspector and assistant inspector, whose expenses provision was made in the estimates this year, been appointed; and, if so, what was the precise nature of the d allotted to them?—Mr. GERALD BALFOUR answered: An inspecto been appointed and arrangements are being proceeded with as t assistant inspector. It is the duty of the inspector to advise Local Government Board as to the administration of the Sale of and Drugs Acts and similar Acts, to deal with matters relating t purity and adulteration of food which are brought to the Bo notice by public analysts, medical officers of health and other obtain information upon special questions relating to the purity adulteration of food and the use of deleterious substances the and to make suitable inquiries and investigations for this pur The inspector will make a report, which will be included in the an report of the Board's medical officer, under whose direction he will

THURSDAY, AUGUST 10TH.

Sterilised Fluids.

Sir HENRY KIMBER asked the Secretary of State for War whethe accordance with the recommendation of the Advisory Medical B that all fluids employed as drinks at manœuvres, on service abroad, on active service should be sterilised by heat, suitable apparatus equipment for this purpose had been issued to the whole of the Bri troops in India and South Africa for service in the field an manœuvres; whether the service of such sterilised fluids had intrusted to specially trained men, having no other duties, each unit, as recommended by the Commission on Dysen and Enteric Fever appointed by the Secretary of State War, August, 1900; whether such specially trained men placed under the direct supervision and responsibility of offi of each unit; and whether the regulations revised in the direc of devolving responsibility upon non-medical officers in the su vision of sanitary services in barracks and camps had been issue Mr. ARNOLD-FORSTER answered: My honourable friend is mistake supposing that the Advisory Board made such a sweeping rec mendation as that stated in the question. Trials were recommen and these have been made, both on service and at manœuvres; fur investigations are still in progress. Heat sterilisation is being lar carried out at various places abroad, including India and South Afr The supervision of water-supplies and methods of water sterilisat where required, are in the hands of the local authorities and sanit officers have been appointed at home and abroad, among whose spe duties are the periodical examination of the drinking water-supp and the diffusion of knowledge of practical sanitary procedure am officers and men. The regulations referred to are contained in provisional issue of Combined Training, Part VII., Section promulgated with Army Orders of March, 1903.

Vaccination Defaulters at Derby.

Sir THOMAS ROE asked the Secretary of State for the Home Dep ment whether his attention had been drawn to the fact that distra warrants were about to be enforced against some 50 vaccinat defaulters at Derby, out of more than 20,000 who were liable to penalty for non-vaccination; and whether he would explain w Derby had been selected for the enforcement of penalties un the Vaccination Acts whilst in other large towns, where the vacci tion default was much greater, such measures were not resorted to Mr. AKERS-DOUGLAS replied: My attention was called by the Lo Government Board to the fact that no attempt was being made by t Derby police to enforce the orders of the magistrates in vaccinat cases and I have been for some time in communication with the Der watch committee on the subject. I am glad to learn that an effort now to be made to carry out the law. I have no information as to t number of defaulters in Derby who have not been prosecuted but if t number suggested by the honourable Member is even approximat accurate it points strongly to the evil which results from the failure enforce the law. I am in communication with the watch committ of another town on the same subject but I know of no other lar towns where the police have so entirely failed to enforce the orders the justices as they have at Derby.

Dogs for Vivisection.

Mr. ELLIS GRIFFITH asked the Secretary of State for the Hon Department whether his attention had been called to the fact that do were bred specially for the purpose of vivisection at the Brockwell H and other farm laboratories; and whether he would cause a return be made of the places at which dogs were being specially bred for th purpose, the laboratories at which experiments were performed them, and the nature and purposes of such experiments.—Mr. AKER DOUGLAS answered: I have made inquiries and I understand that do have been bred at Brockwell Hall and that some of the dogs so bre have been used for experiments in the laboratories. I do not think is of material importance whether dogs which are used for purposes experiment are bred on the premises or imported from elsewhere an as it is not a matter over which I have any control I fear I cann undertake to furnish the return suggested by the honourable Member.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

CHAULMOOGRA OIL AND SYPHILIS

To the Editors of THE LANCET

SIRS,—With reference to the query in THE LANCET of August 12th by Dr Jos Fr von Crippa, regarding the therapeutic properties, &c, of chaulmoogra oil I may say that throughout a protracted residence in India, during which much attention was devoted by me to indigenous drugs, I never heard of this oil being used by European or native practitioners in the treatment of syphilis, but it had considerable repute as an internal or external remedy in leprosy and skin diseases In the year 1856 there appeared in the *Indian Annals of Medical Science* an article regarding its use in the treatment of secondary syphilis but this notice does not appear to have led to any practical results Further remarks regarding the medicinal effects of chaulmoogra, as used in the East, &c, will be found in an article by Dr F Mouat in the *Indian Annals of Medical Science* for 1854 and in a paper by Dr Hobson in the *Edinburgh Medical Journal* for 1855 "The Pharmacopœia of India' (1868), p 440, "Bengal Dispensatory' (1842), p 206, and "Pharmacographia Indica" (1890), vol i, p 142, may also be consulted

I am, Sirs, *yours faithfully,*

GEORGE BIDIE, C I E,

August 12th, 1905 Surgeon General.

To the Editors of THE LANCET

SIRS,—In reply to the inquiry in THE LANCET of August 12th, 1905, p. 498, as to the therapeutic action, active principle, and general characters of oleum gynocardiæ (chaulmoogra oil) especially in the treatment of syphilis, I should like to say that I have searched in vain for details of the use of chaulmoogra oil in syphilis Martindale's "Extra Pharmacopœia" mentions secondary syphilis among other diseases for the treatment of which it is useful and gives several references to medical literature one of which may relate to its use in syphilis There are one or two points about chaulmoogra oil which are worthy of notice The oil has been described in text-books as the product of the seeds of *Gynocardia odorata*, but as a matter of fact its origin is doubtful According to Mr E M Holmes curator of the Museum of the Pharmaceutical Society (*Pharmaceutical Journal*, [4], x, p 522), three varieties of seeds pass under the name chaulmoogra These are *Gynocardia odorata*, R Br, genuine chaulmoogra seeds growing in Eastern India, *Hydnocarpus anthelmintica*, Pierre, a Siamese product, and *H wightiana*, Blume, a native of Western India, the oil of which is employed on the Malabar coast in cutaneous diseases and ophthalmia and for ulcers on the feet It has been taken internally for leprosy, syphilis, and rheumatism, but, like chaulmoogra oil, acts occasionally as a gastro intestinal irritant (Watt, Dictionary of Economic Products of India, vol iv, p 309) The drug finds a place in the Pharmacopœia of India and much of the published literature refers to its value in the treatment of cutaneous diseases, particularly leprosy The ointment appears to be the most valued preparation of chaulmoogra oil, but it is given internally in the form of capsules or a milk emulsion in doses of from 2 to 15 grains Saline aperients should be given at the same time The therapeutic value of the plants which yield the oil would appear to be similar, but more definite information is required on this point The most recent work on chaulmoogra oil is that of Dr F B Power and Mr F H Gornall (Proceedings of the Chemical Society, 20, 135) who differ from other authorities in almost all essential points Thus they state that the plant which yields the chaulmoogra oil of commerce is *Taraktogenos Kurzii* (King), a native of Burma, and not *Gynocardia odorata*, R Br The seeds of *Taraktogenos Kurzii* contain a hydrolytic enzyme and an unstable cyanogen compound which react to form hydrogen cyanide All previous workers have ascribed the therapeutic activity of the drug to "gynocardic acid, but Dr Power and Mr Gornall consider this substance to be a mixture of several fatty acids one of which they have isolated and named chaulmoogric acid It would appear therefore, that the text books are uniformly wrong in describing the source and active principle of chaulmoogra oil The drug has so great a reputation in India that a comparative pharmacological investigation of the products of the various plants yielding commercial chaulmoogra oil seems to be desirable The results of Dr Power and Mr Gornall require to be supplemented by a comparative pharmacological investigation of the so called active principle "gynocardic acid' and chaulmoogric acid —I am, Sirs, yours faithfully,

SEARCHLIGHT

A PROBLEM IN ACOUSTICS

To the Editors of THE LANCET

SIRS,—I shall be much gratified if any of your readers can explain the *cause* of the following phenomenon I have asked several aurists but not one of them could give me a definite reply The majority confessed their ignorance One said that my auditory canal must be abnormally sensitive Another said it might be a "muscle tone' but as he had forgotten what exactly was a muscle tone we "got no forrader" If I advance my jaw to its fullest extent and bite upon the upper lip I get a tinnitus in both ears The sound is like the cry of a bat, an extremely high note, which I have copied exactly on a Galton's whistle If I keep the jaw *fixed in the* above position the sound gradually lessens and dies away in 20 seconds The same thing obtains, but to a less extent, if I open widely my mouth when eating These motions, doubtless, put pressure upon the Eustachian tubes and I can conceive that an impulse may be imparted to the contained air, but although I know little about the ear I do know something of acoustics and I *cannot see how* such an impulse can give rise to a musical note lasting 20 seconds —I am, Sirs, yours faithfully,

August 14th, 1905 A P S

*** A muscle tone is the tone produced by the contraction of a muscle and is, we believe one of 16 vibrations a second But the note of a bat is almost the highest audible sound Possibly the sound heard by our correspondent is caused by the air passing through a small perforation in the membrana tympani Perhaps some of our readers can suggest another explanation.—ED L.

THE TREATMENT OF MEDICAL MEN AT HARROGATE BATHS

To the Editors of THE LANCET

SIRS,—Some days ago on arrival here I went to the manager's office at the Royal Baths to ask for the usual pass to get the waters and book of six free tickets for baths, producing the cover of my last year's pass I was curtly informed by the present manager that as I was not in active private practice and that expenses were being curtailed I could not be granted them, I suppose on the principle that new brooms sweep clean I pointed out that his predecessor last year had given them without any demur and that no objection had ever been made to my getting free passes at any of the other English or continental spas that I had been to, however, he was obdurate I think such action commercially impolitic and ungrateful to our profession and one cannot wonder at the resort of so many members to foreign spas where they are treated with every consideration I presume also that the fact of my having served my country for over 27 years abroad with some distinction would in these days militate against any such trifling concession I merely draw attention to it to save any others of my *confrères* exposing themselves to a similar rebuff

I am, Sirs, yours faithfully,

M A, M D, M R C S Eng

August 7th, 1905 (Lieut Col (Retired), I M Service)

A SCREW CORKED STOPPER AND BOTTLE

APART from the use of antimony sulphide in the red rubber ring, rubber itself is likely to impart a disagreeable taste to liquids with which it comes into contact This may be avoided, of course, by substituting a cork ring but the material must be of a selected kind in order that it may form an air tight joint when the stopper is screwed down We were at first sceptical that cork could be successfully employed in this way owing to the irregularities in its structure By submitting, however, the cork to a series of pressure trials in the first instance, and by adopting a properly constructed neck on the bottle, we find that Messrs Margett and Mitchell of 47, Tooley street, London, S E, have produced a satisfactory screw stopper with a cork ring We tested it by placing in the bottle some water under slight pressure of carbonic acid gas After the lapse of several weeks the water was perfectly brisk and sparkling, so that there could not have been any serious leakage Nor had the taste of the water deteriorated For preserving aerated beverages we may conclude that cork is superior to rubber owing to the fact that the latter material, though probably forming a more secure joint, has a tendency to taint the liquid

PREMATURE BALDNESS

To the Editors of THE LANCET

SIRS,—Could any of your readers tell me whether they have known any internal treatment of any avail for premature loss of hair? I know that in text books on the subject our dermatologists can recommend nothing except the giving of a drug to improve the tone of the system, if such need exists, or to alter any constitutional tendency that a patient might show In the case of an individual who seems in perfect health is there anything else one can do besides applying stimulating liniments? I have no faith in any internal treatment, but thought that some other medical man might be able to give me a wrinkle on the subject

I am Sirs, yours faithfully,

Halton Chambers, King street, W C C STANFORD READ

"INFAMOUS CONDUCT'

To the Editors of THE LANCET

SIRS —As considerable haziness exists amongst junior practitioners as to what constitutes "infamous conduct" in a professional sense, it would be very acceptable to many if the registrar of the General Medical Council or some *other* expert would define and tabulate, especially noting what constitutes sufficient grounds for removal from the Register

I am, Sirs, yours faithfully,

INQUIRER

August 15th, 1905

◆

Mr L E Laurie —Our correspondent's idea is not a bad one, but there are already many bottles for poisons either made of a particular shape or with some particular kind of stopper which should prevent mistakes Perhaps the commonest cause of poisoning is when careless people put poison, as carbolic acid, into gingerbeer bottles or some other kind of bottle which has held a harmless material previously.

Holiday.—In the absence of any provision with regard to holidays in the usual agreement with an assistant it is customary for the principal to allow his assistant a holiday of about two weeks and if any help is required during his absence it should be paid for by the principal. The salary would, of course, be paid to the assistant just the same during absence.

Mr L. Broughton.—Clearly there will be variation.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (21st).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.) Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physician, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.).

TUESDAY (22nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.) FRIDAY (25th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.)

SATURDAY (26th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.)

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (21st).—POST GRADUATE COLLEGE (West London Hospital, Hammersmith road, W.)—3 P.M. Mr Paget: Surgical Cases in the Wards.

TUESDAY (22nd).—POST GRADUATE COLLEGE (West London Hospital, Hammersmith road, W.) 5 P.M. Dr Robinson On Gynæcology.

WEDNESDAY (23rd).—POST GRADUATE COLLEGE (West London Hospital, Hammersmith road, W.)—4.15 P.M. Dr Russell Medical Cases.

THURSDAY (24th).—POST GRADUATE COLLEGE (West London Hospital, Hammersmith road, W.)—5 P.M. Dr Davis Tonsillitis and its Treatment.

FRIDAY (25th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith road, W.)—5 P.M. Lecture:—Mr Paget Surgical Cases.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1905, which was completed with the issue of June 24th, and the Title-page to the Volume, were given in THE LANCET of July 1st.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1905 are now ready. Bound in cloth, gilt lettered, price 18*s*., carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s*., by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31 Rue Bapts, Asnières, Paris.

An Address
ON
EVOLUTION.

Delivered before the British Association for the Advancement of Science, Part I. at Cape Town on August 15th, and Part II. at Johannesburg on August 30th, 1905,

BY PROFESSOR G. H. DARWIN, M.A., LL.D., PH.D., F.R.S.,
THE PRESIDENT.

PART I.

GENTLEMEN,—Bartholomeu Diaz, the discoverer of the Cape of Storms, spent 16 months on his voyage, and the little flotilla of Vasco da Gama, sailing from Lisbon on July 8th, 1497, only reached the Cape in the middle of November. These bold men, sailing in their puny fishing smacks to unknown lands, met the perils of the sea and the attacks of savages with equal courage. How great was the danger of such a voyage may be gathered from the fact that less than half the men who sailed with da Gama lived to return to Lisbon. 408 years have passed since that voyage, and a ship of 13,000 tons has just brought us here, in safety and luxury, in but little more than a fortnight. How striking are the contrasts presented by these events! On the one hand compare the courage, the endurance, and the persistence of the early navigators with the little that has been demanded of us; on the other hand, consider how much man's power over the forces of Nature has been augmented during the past four centuries. The capacity for heroism is probably undiminished, but certainly the occasions are now rarer when it is demanded of us. If we are heroes, at least but few of us ever find it out, and when we read stories of ancient feats of courage it is hard to prevent an uneasy thought that, notwithstanding our boasted mechanical inventions, we are perhaps degenerate descendants of our great predecessors. Yet the thought that to-day is less romantic and less heroic than yesterday has its consolation, for it means that the lot of man is easier than it was. Mankind, indeed, may be justly proud that this improvement has been due to the successive efforts of each generation to add to the heritage of knowledge handed down to it by its predecessors, whereby we have been born to the accumulated endowment of centuries of genius and labour.

I am told that in the United States the phrase "I want to know" has lost the simple meaning implied by the words and has become a mere exclamation of surprise. Such a conventional expression could hardly have gained currency except amongst a people who aspire to knowledge. The dominance of the European race in America, Australasia, and South Africa has no doubt arisen from many causes, but amongst these perhaps the chief one is that not only do "we want to know," but also that we are determined to find out. And now within the last quarter of a century we have welcomed into the ranks of those who "want to know" an Oriental race, which has already proved itself strong in the peaceful arts of knowledge. I take it, then, that you have invited us because you want to know what is worth knowing; and we are here because we want to know you, to learn what you have to tell us, and to see that South Africa of which we have heard so much. The hospitality which you are offering us is so lavish, and the journeys which you have organised are so extensive, that the cynical observer might be tempted to describe our meeting as the largest picnic on record. Although we intend to enjoy our picnic with all our hearts, yet I should like to tell the cynic, if he is here, that perhaps the most important object of these conferences is the opportunity which they afford for personal intercourse between men of like minds who live at the remotest corners of the earth. We shall pass through your land with the speed and the voracity of a flight of locusts; but, unlike the locust, we shall, I hope, leave behind us permanent fertilisation in the form of stimulated scientific and educational activity. And this result will ensue whether or not we who have come from Europe are able worthily to sustain the lofty part of prophets of science. We shall try our best to play to your satisfaction on the great stage upon which you call on us to act, and if when we are gone you shall, amongst yourselves, pronounce the performance a poor one, yet the fact will remain that the meeting has embodied in a material form the desire that the progress of this great continent shall not be merely material; and such an aspiration secures its own fulfilment. However small may be the tangible results of our meeting, we shall always be proud to have been associated with you in your efforts for the advancement of science.

We do not know whether the last hundred years will be regarded for ever as the *sæculum mirabile* of discovery, or whether it is but the prelude to yet more marvellous centuries. To us living men, who scarcely pass a year of our lives without witnessing some new marvel of discovery or invention, the rate at which the development of knowledge proceeds is truly astonishing; but from a wider point of view the scale of time is relatively unimportant, for the universe is leisurely in its procedure. Whether the changes which we witness be *fast* or *slow* they form a part of a long sequence of events which begin in some past of immeasurable remoteness and tend to some end which we cannot foresee. It must always be profoundly interesting to the mind of man to trace successive cause and effect in the chain of events which make up the history of the earth and all that lives on it, and to speculate on the origin and future fate of animals and of planets, suns, and stars. I shall try, then, to set forth in my address some of the attempts which have been made to formulate evolutionary speculation. This choice of a subject has, moreover, been almost forced on me by the scope of my own scientific work and it is, I think, justified by the name which I bear. It will be my fault and your misfortune if I fail to convey to you some part of the interest which is naturally inherent in such researches.

The man who propounds a theory of evolution is attempting to reconstruct the history of the past by means of the circumstantial evidence afforded by the present. The historian of man, on the other hand, has the advantage over the evolutionist in that he *has* the written records of the past on which to rely. The discrimination of the truth from amongst discordant records is frequently a work demanding the highest qualities of judgment; yet when this end is attained it remains for the historian to convert the arid skeleton of facts into a living whole by clothing it with the flesh of human motives and impulses. For this part of his task he needs much of that power of entering into the spirit of other men's lives which goes to the making of a poet. Thus the historian should possess not only the patience of the man of science in the analysis of facts, but also the imagination of the poet to grasp what the facts have meant. Such a combination is rarely to be found in equal perfection on both sides and it would not be hard to analyse the works of great historians so as to see which quality was predominant in each of them. The evolutionist is spared the surpassing difficulty of the human element, yet he also needs imagination, although of a different character from that of the historian. In its lowest form his imagination is that of the detective who reconstructs the story of a crime: in its highest it demands the power of breaking loose from all the trammels of convention and education and of imagining something which has never occurred to the mind of man before. In every case the evolutionist must form a theory for the facts before him, and the great theorist is only to be distinguished from the fantastic fool by the sobriety of his judgment—a distinction, however, sufficient to make one rare and the other only too common.

The test of a scientific theory lies in the number of facts which it groups into a connected whole; it ought besides to be fruitful in pointing the way to the discovery and coördination of new and previously unsuspected facts. Thus a good theory is in effect a cyclopædia of knowledge, susceptible of indefinite extension by the addition of supplementary volumes. Hardly any theory is all true and many are not all false. A theory may be essentially at fault and yet point the way to truth and so justify its temporary existence. We should not, therefore, totally reject one or other of two rival theories on the ground that they seem, with our present knowledge, mutually inconsistent, for it is likely that both may contain important elements of truth. The theories of which I shall have to speak hereafter may often appear discordant with one another according to our present lights. Yet we must not scruple to pursue the several divergent lines of thought to their logical conclusions, relying on future discovery to eliminate the false and to reconcile together the truths which form part of each of them. In the mouths of the unscientific evolution is often spoken of as almost synonymous with the evolution of the various species of animals on the earth and this again is sometimes thought to be practically the same thing as the theory of natural selection. Of course, those who are conversant with the history of scientific ideas are aware that a belief in the gradual and orderly transformation of Nature, both animate and inanimate, is of great antiquity. We may liken the facts on which theories of evolution are based to a confused heap of beads, from which a keen-sighted searcher after truth picks out and strings together a few which happen to catch his eye as possessing certain resemblances. Until recently theories of evolution in both realms of Nature were partial and discontinuous and the chains of facts were correspondingly short and disconnected. At length the theory of natural selection, by formulating the cause of the divergence of forms in the organic world from the parental stock, furnished the naturalist with a clue by which he examined the disordered mass of facts before him, and he was thus enabled to go far in deducing order where chaos had ruled before, but the problem of reducing the heap to perfect order will probably baffle the ingenuity of the investigator for ever. So illuminating has been this new idea that, as the whole of nature has gradually been re-examined by its aid, thousands of new facts have been brought to light and have been strung in due order on the necklace of knowledge. Indeed, the transformation resulting from the new point of view has been so far-reaching as almost to justify the misapprehension of the unscientific as to the date when the doctrines of evolution first originated in the mind of man.

It is not my object, nor indeed am I competent, to examine the extent to which the theory of natural selection has needed modification since it was first formulated by my father and Wallace. But I am surely justified in maintaining that the general principle holds its place firmly as a permanent acquisition to modes of thought. Evolutionary doctrines concerning inanimate nature, although of much older date than those which concern life, have been profoundly affected by the great impulse of which I have spoken. It has thus come about that the origin and history of the chemical elements and of stellar systems now occupy a far larger space in the scientific mind than was formerly the case. The subject which I shall discuss to-night is the extent to which ideas, parallel to those which have done so much towards elucidating the problems of life, hold good also in the world of matter; and I believe that it will be possible to show that in this respect there exists a resemblance between the two realms of Nature, which is not merely fanciful. It is proper to add that as long ago as 1873 Baron Karl du Prel discussed the same subject from a similar point of view in a book entitled "The Struggle for Life in the Heavens."[1] Although inanimate matter moves under the action of forces which are incomparably simpler than those governing living beings, yet the problems of the physicist and the astronomer are scarcely less complex than those which present themselves to the biologist. The mystery of life remains as impenetrable as ever and in his evolutionary speculations the biologist does not attempt to explain life itself, but, adopting as his unit the animal as a whole, discusses its relationships to other animals and to the surrounding conditions. The physicist, on the other hand, is irresistibly impelled to form theories as to the intimate constitution of the ultimate parts of matter and he desires further to piece together the past histories and the future fates of planets, stars, and nebulæ. If, then, the speculations of the physicist seem in some respects less advanced than those of the biologist, it is chiefly because he is more ambitious in his aims. Physicists and astronomers have not yet found their Johannesburg or Kimberley; but, although we are still mere prospectors, I am proposing to show you some of the dust and diamonds which we have already extracted from our surface mines. The fundamental idea in the theory of natural selection is the persistence of those types of life which are adapted to their surrounding conditions, and the elimination by extermination of ill-adapted types. The struggle for life amongst forms possessing a greater or less degree of adaptation to slowly varying conditions is held to explain the gradual transmutation of species. Although a different phraseology is used when we speak of the physical world, yet the idea is essentially the same.

The point of view from which I wish you to consider the phenomena of the world of matter may be best explained if, in the first instance, I refer to political institutions, because we all understand, or fancy we understand, something of politics, whilst the problems of physics are commonly far less familiar to us. This illustration will have a further advantage in that it will not be a mere parable, but will involve the fundamental conception of the nature of evolution. The complex interactions of man with man in a community are usually described by such comprehensive terms as the State, the Commonwealth, or the Government. Various States differ widely in their constitution and in the degree of the complexity of their organisation, and we classify them by various general terms, such as autocracy, aristocracy, or democracy, which express somewhat loosely their leading characteristics. But for the purpose of showing the analogy with physics, we need terms of wider import than those habitually used in politics. All forms of the State imply inter-relationship in the actions of men, and action implies movement. Thus the State may be described as a configuration or arrangement o a community of men; or we may say that it implies definite mode of motion of man—that is to say, an organise scheme of action of man on man. Political history gives a account of the gradual changes in such configurations o modes of motion of men as have possessed the quality o persistence or of stability to resist the disintegrating in fluence of surrounding circumstances. In the world of li the naturalist describes those forms which persist as species similarly the physicist speaks of stable configurations o modes of motion of matter; and the politician speaks o States. The idea at the base of all these conceptions is tha of stability, or the power of resisting disintegration. I other words, the degree of persistence or permanence of species, of a configuration of matter, or of a State depend on the perfection of its adaptation to its surroundin conditions.

If we trace the history of a State we find the degree o its stability gradually changing, slowly rising to a maximum and then slowly declining. When it falls to nothing revolution ensues and a new form of government is estab lished. The new mode of motion or government has at firs but slight stability, but it gradually acquires strength an permanence, until in its turn the slow decay of stability lead on to a new revolution. Such crises in political history ma give rise to a condition in which the State is incapable o perpetuation by transformation. This occurs when a savag tribe nearly exterminates another tribe and leads the fev survivors into slavery; the previous form of government the becomes extinct. The physicist, like the biologist and th historian, watches the effect of slowly varying external conditions; he sees the quality of persistence or stabilit gradually decaying until it vanishes, when there ensues wha is called, in politics, a revolution.

These considerations lead me to express a doubt whethe biologists have been correct in looking for continuous transformation of species. Judging by analogy we should rathe expect to find slight continuous changes occurring during a long period of time, followed by a somewhat sudden transformation into a new species or by rapid extinction. However this may be, when the stability of a mode of motio vanishes the physicist either finds that it is replaced by a new persistent type of motion adapted to the changed conditions, or perhaps that no such transformation is possible and that the mode of motion has become extinct. The evanescent type of animal life has often been preserved fo us, fossilised in geological strata; the evanescent form of government is preserved in written records or in the customs of savage tribes; but the physicist has to pursue his investigations without such useful hints as to the past. The time-scale in the transmutation of species of animals is furnished by the geological record, although it is not possible to translate that record into years. As we shall see hereafter, the time needed for a change of type in atoms or molecules may be measured by millionths of a second, while in the history of the stars continuous changes occupy millions of years. Notwithstanding this gigantic contrast in speed, yet the process involved seems to be essentially the same. It is hardly too much to assert that, if the conditions which determine stability of motion could be accurately formulated throughout the universe, the past history of the cosmos and its future fate would be unfolded. How indefinitely far we stand removed from such a state of knowledge will become abundantly clear from the remainder of my address.

---

[1] Der Kampf um's Dasein am Himmel (zweite Auflage), Denicke, Berlin, 1876.

The study of stability and instability then furnishes the problems which the physicist and biologist alike attempt to solve. The two classes of problems differ principally in the fact that the conditions of the world of life are so incomparably more intricate than those of the world of matter that the biologist is compelled to abandon the attempt to determine the absolute amount of the influence of the various causes which have affected the existence of species. His conclusions are merely qualitative and general and he is almost universally compelled to refrain from asserting even in general terms what are the reasons which have rendered one form of animal life stable and persistent and another unstable and evanescent. On the other hand, the physicist, as a general rule, does not rest satisfied unless he obtains a quantitative estimate of various causes and effects on the systems of matter which he discusses. Yet there are some problems of physical evolution in which the conditions are so complex that the physicist is driven, as is the biologist, to rest satisfied with qualitative rather than quantitative conclusions. But he is not content with such crude conclusions except in the last resort and he generally prefers to proceed by a different method. The mathematician mentally constructs an ideal mechanical system or model which is intended to represent in its leading features the system he wants to examine. It is often a task of the utmost difficulty to devise such a model and the investigator may perchance unconsciously drop out as unimportant something which is really essential to represent actuality. He next examines the conditions of his ideal system and determines, if he can, all the possible stable and unstable configurations, together with the circumstances which will cause transitions from one to the other. Even when the working model has been successfully imagined, this latter task may often overtax the powers of the mathematician. Finally, it remains for him to apply his results to actual matter and to form a judgment of the extent to which it is justifiable to interpret nature by means of his results.

The remainder of my address will be occupied by an account of various investigations which will illustrate the principles and methods which I have now explained in general terms.

The fascinating idea that matter of all kinds has a common substratum is of remote antiquity. In the middle ages the alchemists, inspired by this idea, conceived the possibility of transforming the baser metals into gold. The sole difficulty seemed to them the discovery of an appropriate series of chemical operations. We now know that they were always indefinitely far from the goal of their search, yet we must accord to them the honour of having been the pioneers of modern chemistry. The object of alchemy, as stated in modern language, was to break up or disassociate the atoms of one chemical element into its component parts and afterwards to reunite them into atoms of gold. Although even the dissociative stage of the alchemistic problem still lies far beyond the power of the chemist, yet modern researches seem to furnish a sufficiently clear idea of the structure of atoms to enable us to see what would have to be done to effect a transformation of elements. Indeed, in the complex changes which are found to occur spontaneously in uranium, radium, and the allied metals we are probably watching a spontaneous dissociation and transmutation of elements. Natural selection may seem at first sight as remote as the poles asunder from the ideas of the alchemist, yet dissociation and transmutation depend on the instability and regained stability of the atom and the survival of the stable atom depends on the principle of natural selection. Until some ten years ago the essential diversity of the chemical elements was accepted by the chemist as an ultimate fact, and indeed the very name of atom, or that which cannot be cut, was given to what was supposed to be the final indivisible portion of matter. The chemist thus proceeded in much the same way as the biologist who, in discussing evolution, accepts the species as his working unit. Accordingly, until recently the chemist discussed working models of matter of atomic structure and the vast edifice of modern chemistry has been built with atomic bricks. But within the last few years the electrical researches of Lenard, Roentgen, Becquerel, the Curies, of my colleagues Larmor and Thomson, and of a host of others, have shown that the atom is not indivisible and a flood of light has been thrown thereby on the ultimate constitution of matter. Amongst all these fertile investigators it seems to me that Thomson stands pre-eminent, because it is principally through him that we are to-day in a better position for picturing the structure of an atom than was ever the case before. Even if I had the knowledge requisite for a complete exposition of these investigations the limits of time would compel me to confine myself to those parts of the subject which bear on the constitution and origin of the elements.

It has been shown, then, that the atom, previously supposed to be indivisible, really consists of a large number of component parts. By various convergent lines of experiment it has been proved that the simplest of all atoms—namely, that of hydrogen—consists of about 800 separate parts; while the number of parts in the atom of the denser metals must be counted by tens of thousands. These separate parts of the atom have been called corpuscles or electrons, and may be described as particles of negative electricity. It is paradoxical, yet true, that the physicist knows more about these ultra-atomic corpuscles and can more easily count them than is the case with the atoms of which they form the parts. The corpuscles, being negatively electrified, repel one another just as the hairs on a person's head mutually repel one another when combed with a vulcanite comb. The mechanism is as yet obscure whereby the mutual repulsion of the negative corpuscles is restrained from breaking up the atom, but a positive electrical charge or something equivalent thereto must exist in the atom so as to prevent disruption. The existence in the atom of this community of negative corpuscles is certain and we know further that they are moving with speeds which may in some cases be comparable to the velocity of light—namely, 200,000 miles a second. But the mechanism whereby they are held together in a group is hypothetical.

It is only just a year ago that Thomson suggested, as representing the atom, a mechanical or electrical model the properties of which could be accurately examined by mathematical methods. He would be the first to admit that his model is at most merely a crude representation of actuality, yet he has been able to show that such an atom must possess mechanical and electrical properties which simulate, with what Whetham describes as "almost Satanic exactness," some of the most obscure and yet most fundamental properties of the chemical elements. "Se non è vero, è ben trovato," and we are surely justified in believing that we have the clue which the alchemists sought in vain. Thomson's atom consists of a globe charged with positive electricity, inside which there are some thousand or thousands of corpuscles of negative electricity revolving in regular orbits with great velocities. Since two electrical charges repel one another if they are of the same kind, and attract one another if they are of opposite kinds, the corpuscles mutually repel one another, but all are attracted by the globe containing them. The forces called into play by these electrical interactions are clearly very complicated and you will not be surprised to learn that Thomson found himself compelled to limit his detailed examination of the model atom to one containing about 70 corpuscles. It is indeed a triumph of mathematical power to have determined the mechanical conditions of such a miniature planetary system as I have described.

It appears that there are definite arrangements of the orbits in which the corpuscles must revolve if they are to be persistent or stable in their motions. For the purpose of general discussion, which is all that I shall attempt, you may take it that the number of corpuscles in such a community is fixed, and we may state that definite numbers of corpuscles are capable of association in stable communities of definite types. An infinite number of communities are possible, possessing greater or lesser degrees of stability. Thus the corpuscles in one such community might make thousands of revolutions in the orbits before instability declared itself; such an atom might perhaps last for a long time as estimated in millionths of seconds, but it must finally break up and the corpuscles must disperse or rearrange themselves after the ejection of some of their number. We are thus led to conjecture that the several chemical elements represent those different kinds of communities of corpuscles which have proved by their stability to be successful in the struggle for life. If this is so, it is almost impossible to believe that the successful species have existed for all time and we must hold that they originated under conditions about which I must forbear to follow Sir Norman Lockyer in speculating. But if the elements were not eternal in the past we must ask whether there is reason to believe that they will be eternal in the future. Now, although the conception of the decay of an element and its spontaneous transmutation into another element would have seemed absolutely repugnant to the chemist until recently; yet analogy with other moving systems seems to suggest that the elements are not eternal. At any rate, it is of interest to pursue to its end the history of the model atom which has proved to be so successful in imitating the properties of matter. The laws which govern electricity in motion indicate that such an atom must be radiating or losing energy, and therefore a time must come when it will run down, as a clock does. When this time comes it will spontaneously transmute itself into an element which needs less energy than was required in the former state. Thomson conceives that an atom might be constructed after his model so that its decay should be very slow. It might, he thinks, be made to run for a million years but it would not be eternal.

Such a conclusion is an absolute contradiction to all that was known of the elements until recently, for no symptoms of decay are perceived and the elements existing in the solar system must already have lasted for millions of years. Nevertheless, there is good reason to believe that in radium and in other elements possessing very complex atoms we do actually observe that break-up and spontaneous re-arrangement which constitute a transmutation of elements. It is impossible as yet to say how science will solve this difficulty, but future discovery in this field must surely prove deeply interesting. It may well be that the train of thought which I have sketched will ultimately profoundly affect the material side of human life, however remote it may now seem from our experiences of daily life.

I have not as yet made any attempt to represent the excessive minuteness of the corpuscles of the existence of which we are now so confident, but as an introduction to what I have to speak of next it is necessary to do so. To obtain any adequate conception of their size we must betake ourselves to a scheme of threefold magnification. Lord Kelvin has shown that if a drop of water were magnified to the size of the earth the molecules of water would be of a size intermediate between that of a cricket-ball and of a marble. Now each molecule contains three atoms, two being of hydrogen and one of oxygen. The molecular system probably presents some sort of analogy with that of a triple star, the three atoms, replacing the stars, revolving about one another in some sort of dance which cannot be exactly described. I doubt whether it is possible to say how large a part of the space occupied by the whole molecule is occupied by the atoms, but perhaps the atoms bear to the molecule some such relationship as the molecule to the drop of water referred to. Finally, the corpuscles may stand to the atom in a similar scale of magnitude. Accordingly a threefold magnification would be needed to bring these ultimate parts of the atom within the range of our ordinary scales of measurement.

I have already considered what would be observed under the triply powerful microscope and must now return to the intermediate stage of magnification, in which we consider those communities of atoms which form molecules. This is the field of research of the chemist. Although prudence would tell me that it would be wiser not to speak of a subject of which I know so little, yet I cannot refrain from saying a few words. The community of atoms in water has been compared with a triple star, but there are others known to the chemist in which the atoms are to be counted by fifties and hundreds, so that they resemble constellations. I conceive that here again we meet with conditions similar to those which we have supposed to exist in the atom. Communities of atoms are called chemical combinations and we know that they possess every degree of stability. The existence of some is so precarious that the chemist in his laboratory can barely retain them for a moment; others are so stubborn that he can barely break them up. In this case dissociation and reunion into new forms of communities are in incessant and spontaneous progress throughout the world. The more persistent or more stable combinations succeed in their struggle for life and are found in vast quantities, as in the cases of common salt and of the combinations of silicon. But no one has ever found a mine of gun-cotton, because it has so slight a power of resistance. If, through some accidental collocation of elements, a single molecule of gun-cotton were formed, it would have but a short life. Stability is, further, a property of relationship to surrounding conditions; it denotes adaptation to environment. Thus salt is adapted to the struggle for existence on the earth, but it cannot withstand the severer conditions which exist in the sun.

PART II.

GENTLEMEN,—At Cape Town I attempted to make a general survey of evolution in its various branches and laid down certain general propositions as to what seems common to all of them. I then went on to consider how these general laws found an application in the most recent speculations as to the constitution of matter. The atoms of the elements and the molecules of chemical combinations are constructed on so minute a scale that it is no easy task to picture them to our minds. On the other hand, we see in the heavens arrangements of matter on a scale so vast that it is equally difficult to grasp. Both the inconceivably small and the inconceivably large should fall under a general law, if it is a true one; and the history of satellites, planets, and stars present at least as great an interest as that of atoms and molecules. Accordingly the transition from the small to the large seemed to afford a convenient halting place in my address, and I propose to-night to resume the discussion by considering various theories of celestial evolution. But I will first try to render the point of view intelligible which I desire to take. A short preliminary explanation for those who were not at Cape Town thus becomes necessary. I desire to present the essential features which are common to evolution in all its branches and this may be done most easily by reference to political institutions, because we all fancy we understand something of politics.

The complex interactions of man with man in a community are usually described by such comprehensive terms as "the State," "the Commonwealth," or "the Government." Various States differ widely in their constitution and in the degree of the complexity of their organisation, and we classify them by various general terms, such as "autocracy," "aristocracy," or "democracy," which express somewhat loosely their leading characteristics. But for the purpose of showing the analogy with physics we need terms of wider import than those habitually used in politics. All forms of the State imply inter-relationship in the actions of men and action implies movement. Thus the State may be described as a configuration or arrangement of a community of men; or we may say that it implies a definite mode of motion of men—that is to say, an organised scheme of action of man on man. Political history gives an account of the gradual changes in such configurations or modes of motion of men as have possessed the quality of persistence or of stability to resist the disintegrating influence of surrounding circumstances. In the history of a State we find this stability or power of persistence continually changing. It slowly rises to a maximum and then declines; when it falls to nothing a revolution ensues and a new form of government is established. This new mode of motion of men or government has at first but little stability, but it gradually acquires strength and permanence until in its turn the slow decay in the power of persistence leads on to a new revolution. Such crises in political history may give rise to a condition in which the State is incapable of perpetuation by transformation. This occurs when a savage tribe nearly exterminates another and leads the few survivors into slavery; the previous form of government then becomes extinct.

Now turn to the evolution of the various forms of life. The fundamental idea in the theory of natural selection is the persistence of those types of life which are adapted to their surrounding conditions and the elimination by extermination of the ill-adapted types. The struggle for life amongst forms possessing various degrees of adaptation to slowly varying conditions is held to explain the transmutation of species. Although a different phraseology is used when we speak of the physical world yet the idea is essentially the same. Theories of physical evolution involve the discovery of modes of motion or configurations of matter which are capable of persistence. The physicist describes such types as stable; the biologist calls them species. The physicist, the biologist, and the historian alike watch the effect of slowly varying external conditions; they all observe the rise and decline of stability, with the consequent change of type of motion, transmutation of species, or revolution.

And now after this preface I turn to astronomical theories of evolution. The German astronomer Bode long ago propounded a simple empirical law concerning the distances at which the several planets move about the sun and his formula embraces so large a number of cases with accuracy that we are compelled to believe that it arises in some manner from the primitive conditions of the planetary system. The explanation of the causes which have led to this simple law as to the planetary distances presents an interesting problem and, although it is still unsolved, we may obtain some insight into its meaning by considering what may be called a working model of ideal simplicity. Imagine, then, a sun round which there moves in a circle a single large planet. I will call this planet Jove, because it may be taken as a representative of our largest planet Jupiter. Suppose next that a meteoric stone or small planet is projected in any perfectly arbitrary manner in the same plane in which Jove is moving; then we ask how this third body will move. It appears that under the combined attractions of the sun and Jove the meteoric stone will in general describe an orbit of extraordinary complexity, at one time moving slowly at a great distance from both the sun and Jove, at other times rushing close past one or other of them. As it grazes past Jove or the sun it may often but just escape a catastrophe, but a time will come at length when it runs its chances too fine and comes into actual collision. The individual career of the stone is then ended by absorption and, of course, by far the greater chance is that it will find its Nirvana by absorption in the sun.

Next, let us suppose that instead of one wandering meteoric stone or minor planet there are hundreds of them moving initially in all conceivable directions. Since they are all supposed to be very small, their mutual attractions will be insignificant and they will each move almost as though they were influenced only by the sun and Jove. Most of these stones will be absorbed by the sun and the minority will collide with Jove. When we inquire how long the career of a stone may be we find that it depends on the direction and speed with which it is started, and that by proper adjustment the delay of the final catastrophe may be made as long as we please. Thus by making the delay indefinitely long we reach the conception of a meteoric stone which moves so as never to come into collision with either body. There are, therefore, certain perpetual orbits in which a meteoric stone or minor planet may move for ever without collision. But when such an immortal career has been discovered for our minor planet it still remains to discover whether the slightest possible departure from the prescribed orbit will become greater and greater and ultimately lead to a collision with the sun or Jove, or whether the body will travel so as to cross and recross the exact perpetual orbit, always remaining close to it. If the slightest departure inevitably increases as time goes on the orbit is unstable; if, on the other hand, it only leads to a slight waviness in the path described it is stable.

We thus arrive at another distinction: there are perpetual orbits, but some, and indeed most, are unstable, and these do not offer an immortal career for a meteoric stone; and there are other perpetual orbits which are stable or persistent. The unstable ones are those which succumb in the struggle for life and the stable ones are the species adapted to their environment. If, then, we are given a system of a sun and large planet, together with a swarm of small bodies moving in all sorts of ways, the sun and planet will grow by accretion, gradually sweeping up the dust and rubbish of the system, and there will survive a number of small planets and satellites moving in certain definite paths. The final outcome will be an orderly planetary system in which the various orbits are arranged according to some definite law. There is hardly room for doubt that if a complete solution for our solar system were attainable, we should find that the orbits of the existing planets and satellites are numbered amongst the stable perpetual orbits and should thus obtain a rigorous mechanical explanation of Bode's law concerning the planetary distances.

In the first portion of my address I described the orbits in which the corpuscles move in the atoms of matter and drew attention to the resemblance to a planetary system. It may not perhaps be fanciful to imagine that some general mathematical method devised for solving a problem of cosmical evolution may find another application to miniature atomic systems and may thus lead onward to vast developments of industrial mechanics. Science, however diverse its aims, is a whole, and men of science do well to impress on the captains of industry that they should not look askance on those branches of investigation which may seem for the moment far beyond any possibility of practical utility. The theory which I have now explained points to the origin of the sun and planets from gradual accretions of meteoric stones and it makes no claim to carry the story back behind the time when there was already a central condensation or sun about which there circled another condensation or planet. But more than a century ago an attempt had already been made to reconstruct the history back to a yet remoter past and, as we shall see, this attempt was based upon quite a different supposition as to the constitution of the primitive solar system. I myself believe that the theory I have just explained, as well as that to which I am coming, contains essential elements of truth and that the apparent discordances will some day be reconciled. The theory of which I speak is the celebrated nebular hypothesis, first suggested by the German philosopher Kant, and later restated independently and in better form by the French mathematician Laplace.

Laplace traced the origin of the solar system to a nebula or cloud of rarefied gas congregated round a central condensation which was ultimately to form the sun. The whole was slowly rotating about an axis through its centre, and, under the combined influences of rotation and of the mutual attraction of the gas, it assumed a globular form, slightly flattened at the poles. The primeval globular nebula is undoubtedly a stable or persistent figure, and thus Laplace's hypothesis conforms to the general laws which I have attempted to lay down. The nebula must have gradually cooled by radiation into space, and as it did so the gas must necessarily have left some of its spring or elasticity, thus permitting a greater degree of condensation of the whole. The contraction led inevitably to two results: first, the central condensation became hotter; and, secondly, the speed of its rotation became faster. The accelerated rotation led to an increase in the amount of polar flattening and the nebula at length assumed the form of a lens, or of a disk thicker in the middle than at the edges. Assuming the existence of the primitive nebula the hypothesis may be accepted thus far as practically certain.

From this point, however, doubt and difficulty enter into the argument. It is supposed that the nebula became so much flattened that it could not subsist as a continuous aggregation of gas, and a ring of matter detached itself from the equatorial regions. The central portions of the nebula, when relieved of the excrescence, resumed the more rounded shape formerly possessed by the whole. As the cooling continued the central portion in its turn became excessively flattened through the influence of its increased rotation; another equatorial ring then detached itself, and the whole process was repeated as before. In this way the whole nebula was fissured into a number of rings surrounding the central condensation, whose temperature must by then have reached incandescence. Each ring then aggregated itself round some nucleus which happened to exist in its circumference and so formed a subordinate nebula. Passing through a series of transformations like its parent, this nebula was finally replaced by a planet with attendant satellites. The whole process forms a majestic picture of the history of our system. But the mechanical conditions of a rotating nebula are too complex to admit as yet of complete mathematical treatment; and thus in discussing this theory the physicist is compelled in great measure to adopt the qualitative methods of the biologist rather than the quantitative ones which he would prefer. Although the telescope seems to confirm the general correctness of Laplace's hypothesis, yet it is hardly too much to say that every stage in the supposed process presents to us some impossibility. Thus, for example, the ring of Saturn seems to have suggested the theory to Laplace, but to take it as a model leads us straight to a quite fundamental difficulty. If a ring of matter ever concentrates under the influence of its mutual attraction it can only do so round the centre of gravity of the whole ring. Therefore the matter forming an approximately uniform ring, if it concentrates at all, can only fall in on the parent planet and be re-absorbed. Some external force other than the mutual attraction of the matter forming the ring, and therefore not provided by the theory, seems necessary to effect the supposed concentration. The only way of avoiding this difficulty is to suppose the ring to be ill-balanced or lop-sided; in this case, provided the want of balance is pronounced enough, concentration will take place round a point inside the ring but outside the planet. However, this is not the time to pursue these considerations further, yet enough has been said to show that the nebular hypothesis cannot be considered as a connected intelligible whole, however much of truth it may contain.

In the first theory which I sketched as to the origin of the sun and planets we supposed them to grow by the accretions of meteoric wanderers in space, and this hypothesis is apparently in fundamental disagreement with the conception of Laplace, who watches the transformations of a continuous gaseous nebula. I must not pause to consider how these seemingly discordant views may be reconciled but will merely say that I conceive both theories contain important elements of truth. We have seen that in order to explain the genesis of planets according to Laplace's theory the rings must be ill-balanced or even broken. If the ring were so far from being complete as only to cover a small segment of the whole circumference, the true features of the occurrences in the births of planets and satellites might be better represented by conceiving the detached portion of matter to have been more or less globular from the first rather than ring-shaped. Now, this idea introduces us to another group of researches whereby mathematicians have sought to explain the birth of planets and satellites. The solution of the problem of evolution involves the search for those persistent or stable forms which biologists would call species. The species of which I am now going to speak may be grouped in a family which comprises all those various forms which a mass of rotating liquid is capable of assuming under the conjoint influences of gravitation and rotation. If the earth were formed throughout of a liquid of the same density it would be one of the species of this family; and, indeed, these researches date back to the time of Newton, who was the first to explain the figures of planets. The ideal liquid planets we are to consider must be regarded as working models of actuality and inasmuch as the liquid is supposed to be incompressible the conditions depart somewhat widely from those of reality. Hence, when the problem has been solved much uncertainty remains as to the extent to which our conclusions will be applicable to actual celestial bodies.

We begin, then, with a rotating liquid planet like the earth, which is the first stable species of our family. We next impart in imagination more rotation to this planet and find by mathematical calculation that its power of resistance to any sort of disturbance is less than it was. In other words, its stability declines with increased rotation and at length we reach a stage at which the stability just vanishes. At this point the shape is a transitional one, for it is the beginning of a new species with different characteristics from the first and with a very feeble degree of stability or power of persistence. As a still further amount of rotation is imparted the stability of the new species increases to a maximum and then declines until a new transitional shape is reached and a new species comes into existence. In this way we pass from species to species with an ever-increasing amount of rotation. The first or planetary species has a circular equator like the earth; the second species has an oval equator, so that it is something like an egg spinning on its side on a table; in the third species we find that one of the two ends of the egg begins to swell and that the swelling gradually becomes a well-marked protrusion or filament. Finally, the filamentous protrusion becomes bulbous at its end and is only joined to the main mass of liquid by a gradually thinning neck. The neck at length breaks and we are left with two separated masses which may be called planet and satellite. In this ideal problem the successive transmutations of species are brought about by gradual additions to the amount of rotation with which the mass of liquid is endowed. It might seem as if this continuous addition to the amount of rotation were purely arbitrary and could have no counterpart in nature. But real bodies cool and contract in cooling and I must ask you to believe that the effects of an apparently arbitrary increase of rotation may be produced by cooling.

The figures which I succeeded in drawing, by means of rigorous calculation, of the later stages of this course of evolution are so curious as to remind one of some such phenomenon as the protrusion of a filament of protoplasm from a mass of living matter, and I suggest that we may see in this almost life-like process the counterpart of at least one form of the birth of double stars, planets, and satellites. My Cambridge colleague Jeans has also made an interesting contribution to the subject by attacking the far more difficult case where the rotating fluid is a compressible gas. In this case also he finds a family of types but the conception of compressibility introduced a new set of considerations in the transitions from species to species. The problem is, however, of such difficulty that he had to rest content with results which were rather qualitative than strictly quantitative. It cannot be doubted that the supposed Laplacian sequence of events possesses a considerable element of truth, yet these latter schemes of transformation can be followed in closer detail. It seems, then, probable that both processes furnish us with crude models of reality and that in some cases the first, and in others the second, is the better representative. The moon's mass is $\frac{1}{80}$th of that of the earth, whereas the mass of Titan, the largest satellite in the solar system, is $\frac{1}{4600}$th of that of Saturn. On the ground of this great difference between the relative magnitudes of all other satellites and of the moon it is not unreasonable to suppose that the mode of separation of the moon from the earth may also have been widely different. The theory of which I shall have next to speak claims to trace the gradual departure of the moon from an original position not far removed from the present surface of the earth. If this view is correct, we may suppose that the detachment of the moon from the earth occurred as a single portion of matter and not as a concentration of a Laplacian ring. If a planet is covered with oceans of water and air or if it is formed of plastic molten rock tidal oscillations must be generated in its mobile parts by the attractions of its satellites and of the sun. Such movements must be subject to frictional resistance and the planet's rotation will be slowly retarded by tidal friction in much the same way that a fly-wheel is gradually stopped by any external cause of friction. Since action and reaction are equal and opposite, the action of the satellites on the planet, which causes the tidal friction of which I speak, must correspond to a reaction of the planet on the motion of the satellites. At any moment of time we may regard the system composed of the rotating planet with its attendant satellite as a stable species of motion, but the friction of the tides introduces forces which produce a continuous, although slow, transformation in the configuration. It is then clearly of interest to trace backwards in time the changes produced by such a continuously acting cause and to dermine the initial condition from which the system of planet and satellite must have been slowly degrading. We might also look forward and discover whither the transformation tends.

Let us consider, then, the motion of the earth and moon revolving in company round the sun, on the supposition that the friction of the tides in the earth is the only effective cause of change. We are, in fact, to discuss a working model of the system analogous to those of which I have so often spoken before and it must suffice to set forth the result in its main outline as referring only to the past. If we take the "day," regarding it as a period of variable length, to mean the time occupied by a single rotation of the earth on its axis, and the "month," likewise variable in absolute length, to mean the time occupied by the moon in a single revolution round the earth, the number of days in the month expresses the speed of the earth's rotation relatively to the speed of the moon's revolution. Now in our retrospect both day and month are found continuously shortening, but as, on the whole, the month shortens much more quickly than the day the number of days in the month also falls. We may, then, ask at once, What is the initial stage to which the gradual transformation points? I say that on following the argument to its end the system may be traced back to a time when the day and month were identical in length and were both only about four or five of our present hours. The identity of day and month means that the moon was always opposite to the same side of the earth; thus, at the beginning the earth always presented the same face to the moon, just as the moon now always shows the same face to us. Moreover, when the month was only some four or five of our present hours in length the moon must have been only a few thousand miles from the earth's surface—a great contrast with the present distance of 240,000 miles. It might well be argued from this conclusion alone that the moon separated from the earth more or less as a single portion of matter at a time immediately antecedent to the initial stage to which she has been traced. But there exists a yet more weighty argument favourable to this view, for it appears that the initial stage is one in which the stability of the species of motion is tottering, so that the system presents the characteristic of a transitional form, which we have seen to denote a change of type or species in a previous case. In discussing the transformations of a liquid planet we saw the tendency of the single mass to divide into two portions and now we seem to reach a similar crisis from the opposite end, when in retrospect we trace back the system to two masses of unequal sizes in close proximity with one another. The argument almost carries conviction with it, but I have necessarily been compelled to pass over various doubtful points.

Time is wanting to consider other subjects worthy of notice which arise out of this problem, yet I wish to point out the fact that tidal friction is competent to explain the eccentricity of an orbit, because this conclusion has been applied in a manner to which I shall have occasion to return hereafter. If, as has been argued, tidal friction has played so important a part in the history of the earth and moon, it might be expected that the like should be true of the other planets and satellites and of the planets themselves in their relationship to the sun. But numerical examination of the several cases proves conclusively that this cannot have been the case. The relationship of the moon to the earth is, in fact, quite exceptional in the solar system and we have still to rely on such theories as that of Laplace for the explanation of the main outlines of the solar system. I have not yet mentioned the time occupied by the sequence of events sketched out in the various schemes of cosmogony and the question of cosmical time is a thorny and controversial one. Our ideas are absolutely blank as to the time requisite for the evolution either according to Laplace's nebular hypothesis or the meteoritic theory. All we can assert is that they demand enormous intervals of time as estimated in years. The theory of tidal friction stands alone amongst these evolutionary speculations in that we can establish an exact but merely relative time-scale for every stage of the process. Although it is true that the value in years of the unit of time remains unknown, yet it is possible to determine a period in years which must be shorter than that in which the whole history is comprised. If at every moment since the birth of the moon tidal friction had always been at work in such a way as to produce the greatest possible effect, then we should find that 60,000,000 years would be consumed in this portion of evolutionary history. The true period must be much greater, and it does not seem unreasonable to suppose that 500,000,000 to 1,000,000,000 years may have elapsed since the birth of the moon. Such an estimate would not seem extravagant to geologists who have, in various ways, made exceedingly rough determinations of geological periods. As far as my knowledge goes I should say that pure geology points to some period intermediate between 500,000,000 and 1,000,000,000 of years, the upper limit being more doubtful than the lower. Thus far we do not find anything which renders the tidal theory of evolution untenable. But the physicists have formed estimates in other ways which, until recently, seemed to demand in the most imperative manner a far lower scale of time. According to all theories of cosmogony, the sun is a star which became heated in the process of its condensation from a condition of wide dispersion. When a meteoric stone falls into the sun the arrest of its previous motion gives rise to heat, just as the blow of a horse's shoe on a stone makes a spark. The fall of countless meteoric stones, or the condensation of a rarefied gas, was supposed to be the sole cause of the sun's high temperature.

Since the mass of the sun is known the total amount of the heat generated in it, in whatever mode it was formed, can be estimated with a considerable amount of precision. The heat received at the earth from the sun can also be measured with some accuracy and hence it is a mere matter of calculation to determine how much heat the sun sends out in a year. The total heat which can have been generated in the sun divided by the annual output gives a quotient of about 20,000,000. Hence it seemed to be imperatively necessary that the whole history of the solar system should be comprised within some 20,000,000 of years. This argument, which is due to Helmholtz, appeared to be absolutely crushing, and for the last 40 years the physicists have been accustomed to tell the geologists that they must moderate their claims. But for myself I have always believed that the geologists were more nearly correct than the physicists, notwithstanding the fact that appearances were so strongly against them. And now, at length, relief has come to the strained relations between the two parties, for the recent marvellous discoveries in physics show that concentration of matter is not the only source from which the sun may draw its heat. Radium is a substance which is perhaps millions of times more powerful than dynamite. Thus it is estimated that an ounce of radium would contain enough power to raise 10,000 tons a mile above the earth's surface. Another way of stating the same estimate is this: the energy needed to tow a ship of 12,000 tons a distance of 6000 sea miles at 15 knots is contained in 22 ounces of radium. The *Saxon* probably burns 5000 or 6000 tons of coal on a voyage of approximately the same length. Other lines of argument tend in the same direction. Now we know that the earth contains radio-active materials and it is safe to assume that it forms in some degree a sample of the materials of the solar system; hence it is almost certain that the sun is radio-active also. This branch of science is as yet but in its infancy, but we already see how unsafe it is to dogmatise on the potentialities of matter. It appears, then, that the physical argument is not susceptible of a greater degree of certainty than that of the geologists, and the scale of geological time remains in great measure unknown. I have now ended my discussion of the solar system, and must pass on to the wider fields of the stellar universe.

Only a few thousand stars are visible with the unaided eye, but photography has revealed an inconceivably vast multitude of stars and nebulæ, and every improvement in that art seems to disclose yet more and more. It seems useless to consider whether the number of stars has any limit, for infinite number, space, and time transcend our powers of comprehension. We must then make a virtue of necessity, and confine our attention to such more limited views as seem within our powers. A celestial photograph looks at first like a dark sheet of paper splashed with whitewash, but further examination shows that there is method in the arrangement of the white spots. Thus there is order of some sort in the heavens, and although no reason can be assigned for the observed arrangement in any particular case, yet it is possible to obtain general ideas as to the succession of events in stellar evolution. Besides the stars there are numerous streaks, wisps, and agglomerations of nebulosity, whose light we know to emanate from gas. Spots of intenser light are observed in less brilliant regions; clusters of stars are sometimes imbedded in nebulosity, while in other cases each individual star of a cluster stands out clear by itself. These and other observations force on us the conviction that the wispy clouds represent the earliest stage of development, the more condensed nebulæ a later stage, and the stars themselves the last stage. This view is in agreement with the nebular hypothesis of Laplace and we may fairly conjecture that chains and lines of stars represent pre-existing streaks of nebulosity. Change is obviously in progress everywhere as well in each individual nebula and star as in the positions of these bodies relatively to one another. But we are unable even to form conjectures as to the tendency of the evolution which is going on. This being so, we cannot expect, by considering the distribution of stars and nebulæ, to find many illustrations of the general laws of evolution which I have attempted to explain: accordingly I must confine myself to the few cases where we at least fancy ourselves able to form ideas as to the stages by which the present conditions have been reached.

Up to a few years ago there was no evidence that the law of gravitation extended to the stars, and even now there is nothing to prove the transmission of gravity from star to star. But in the neighbourhood of many stars the existence of gravity is now as clearly demonstrated as within the solar system itself. The telescope has disclosed the double character of a large number of stars, and the relative motion of the pairs of companions has been observed with the same assiduity as that of the planets. When the relative orbit of a pair of binary or double stars is examined it is found that the motion conforms exactly to those laws of Kepler which prove that the planets circle round the sun under the action of solar gravitation. A leading characteristic of all these double stars is that the two companions do not differ enormously in mass from one another. In this respect these systems present a strongly marked contrast with that of the sun, attended as it is by relatively insignificant planets.

In the earlier part of my address I showed how theory indicates that a rotating fluid body will as it cools separate into two detached masses. Mathematicians have not yet been able to carry their analysis far enough to determine the relative magnitudes of the two parts, but as far as we can see the results point to the birth of a satellite whose mass is a considerable fraction of that of its parent. Accordingly See (who devotes his attention largely to the astronomy of double stars), Alexander Roberts, and others consider that what they have observed in the heavens is in agreement with the indications of theory. It thus appears that there is reason to hold that double stars have been generated by the division of primitive and more diffused single stars. But if this theory is correct we should expect the orbit of a double star to be approximately circular; yet this is so far from being the case that the eccentricity of the orbits of many double stars exceeds by far any of the eccentricities in the solar system. Now See has pointed out that when two bodies of not very unequal masses revolve round one another in close proximity the conditions are such as to make tidal friction as efficient as possible in transforming the orbit. Hence we seem to see in tidal friction the cause which may have sufficed not only to separate the two component stars from one another, but also to render the orbit eccentric. I have thought it best to deal very briefly with stellar astronomy in spite of the importance of the subject because the direction of the changes in progress is in general too vague to admit of the formation of profitable theories.

We have seen that it is possible to trace the solar system back to a primitive nebula with some degree of confidence and that there is reason to believe that the stars in general have originated in the same manner. But such primitive nebulæ stand in as much need of explanation as their stellar offspring. Thus, even if we grant the exact truth of these theories the advance towards an explanation of the universe remains miserably slight. Man is but a microscopic being relatively to astronomical space and he lives on a puny planet circling round a star of inferior rank. Does it not, then, seem as futile to imagine that he can discover the origin and tendency of the universe as to expect a house fly to instruct us as to the theory of the motions of the planets? And yet, so long as he shall last, he will pursue his search, and will no doubt discover many wonderful things which are still hidden. We may, indeed, be amazed at all that man has been able to find out, but the immeasurable magnitude of the undiscovered will throughout all time remain to humble his pride. Our children's children will still be gazing and marvelling at the starry heavens but the riddle will never be read.

REMOVAL OF A LARGE PIN FROM THE LOWER LOBE OF THE LUNG BY TRANSPLEURAL PNEUMOTOMY.

BY R. HAMILTON RUSSELL, F.R.C.S. ENG.,
SURGEON TO THE ALFRED HOSPITAL, MELBOURNE; CONSULTING SURGEON TO THE MELBOURNE HOSPITAL FOR SICK CHILDREN.

With Notes on the Radiographic Methods employed, by WILLIAM R. FOX, L.R.C.S., L.R.C.P. Edin., *Honorary Physician to the Melbourne Benevolent Asylum.*

(*With Illustrative Plate.*)

I HAVE been unable to discover the record of any case in which the chest has been opened in the free manner employed in this instance for the purpose of extracting a foreign body from the lung and I conclude, therefore, that the features of interest that are presented by it are unique in kind. I am indebted for the earlier notes to Mr. H. W. Bryant, under whose care the boy came in the first instance.

The patient, aged 12 years, was admitted into the Alfred Hospital, Melbourne, under my care on Sept. 12th, 1903, with the following history. Five weeks previously he was sitting in a rocking chair holding in his mouth a large black-headed shawl pin, three inches in length, when the chair was suddenly tilted, and in the effort to save himself the pin disappeared down his trachea without any cough or spasm of the glottis. No symptoms of any kind appeared to have supervened until a week later, when he began to be troubled with a cough, and a week later still the sputa became blood-stained. Three weeks after the occurrence he was examined radioscopically by Mr. W. R. Fox, and the pin was seen to be in the left bronchus, the head lying two and a half inches below the bifurcation, the point projecting into the trachea. It was suggested by Mr. Fox that an attempt should be made to extract the pin with an electro-magnet which he undertook to devise and construct, and as it was thought likely that tracheotomy might be required the patient was admitted under my care into the Alfred Hospital. Without going into unnecessary detail it was found at a subsequent examination made by Mr. Fox that the pin had travelled down into the lower lobe of the lung and that all idea of extracting it through the trachea would have to be abandoned. The boy's symptoms on admission were exceedingly slight; there was a little irritative cough and occasionally a streak of blood was expectorated; there was also a slight irregularity of temperature, which sometimes rose to between 99° and 100° F. at night; otherwise he appeared to be in excellent health and careful auscultation revealed nothing.

On radioscopic examination the following points were noted. The pin was readily seen lying in the lower part of the left lung, the point being directed obliquely upwards towards the trachea (Fig. 1). At each cardiac pulsation the point of the pin rose and fell as though it were resting upon the base of the heart. The position of the head could be easily indicated on the chest wall by examining in two positions, antero-posteriorly and laterally, and marking the spot coinciding with the head in either position. It was then found that when viewed antero-posteriorly the head was about on a level with the eighth rib; when viewed laterally it lay in a vertical plane corresponding to that of the posterior fold of the axilla. The project of extracting the pin through an opening in the chest wall looked as though it should be an easy matter; nevertheless it was novel work, and I had reason to be very glad that before undertaking it upon the living I sought an opportunity of studying the matter in the dead-house.

The results of my experimental investigations with a similar pin and a lung removed from the body were as follows. In the first place, it was clear that the pin had passed into the main bronchus of the lower lobe of the lung, which corresponded exactly with the position of the pin as shown by the rays. Secondly, I ascertained that by grasping the lobe firmly between the fingers and thumb and making a slight rocking movement I was able with a little practice to detect the rigidity caused by the presence of the pin. The observation which was really the most important of all, however, was concerned with the extreme slipperiness of the foreign body in the bronchus. I found that having once grasped the lung containing the pin it would never do to let go or to relax the grasp until the pin was extracted. Anything in the nature of fumbling caused the pin to slip away with great readiness and as it would then be travelling point first, the point being, moreover, in close proximity to the great vessels at the base of the heart, the dangers that might result from maladroit handling were obvious and very real. Upon these considerations the following operation was planned and carried out.

Operation (Oct. 2nd).—The boy being placed on his right side, a free curved incision with the convexity downwards was made and the flap thus marked out was reflected upwards. A portion of the left eighth rib six inches long was then removed from the postero-lateral part of the chest and air was cautiously permitted to enter the pleura through a small puncture. The resulting collapse of the lung was not attended by untoward symptoms and the pleura was opened up to the full extent of the wound. Ample room was afforded; the fingers of the left hand were passed between the lung and the diaphragm, the lower lobe grasped near its root and gently drawn towards the opening. It was now possible to recognise the rigidity caused by the presence of the pin. Maintaining a firm hold with the left hand the position of the head of the pin was ascertained by gently palpating the surface of the lung with the right fingers. A small incision was made in the lung over the pin's head; a sinus forceps, unopened, was pushed in until the pin was felt and by hitching the instrument under the neck of the pin the head was easily lifted out of the wound and the pin was withdrawn. There was no hæmorrhage but it is a notable circumstance that abscess formation had already begun round the foreign body, for when the head of the pin was reached a small quantity of pus (10 or 20 minims) escaped. No suture was put into the very small wound in the lung. The flap of integument was replaced and sutured with the exception of about two inches in the middle. This was left unclosed by sutures and a piece of oiled silk protective was laid over it before the dressings were applied; by this means free escape of air from the pleura was insured, while the piece of protective by its valvular action would impede the passage of air back into the pleura and thus encourage the expansion of the lung. Immediately after the operation there was great restlessness, which was relieved by a small dose of morphine, and for two or three days there were some dyspnœa and general distress, which, however, steadily diminished. There was also moderate fever, the temperature ranging between 99° and 100°, and examination of the chest revealed very general consolidation of the lobe from which the pin had been extracted. By the fourth day, however, convalescence fairly set in, the temperature became normal, the appetite returned, and all discomfort vanished. The wound in the chest wall did not pursue a strictly aseptic course and there was some suppuration about the stitches. This I attribute to accidental infection from the pus round the pin during the operation. Happily no suppuration of the pleura took place and healing progressed kindly and rapidly under a moist dressing, so that the boy was able to leave the hospital perfectly well 12 days after the operation. The very difficult problem of photographing so slender an object as a pin while it was subject to constant movement produced by both the cardiac and respiratory cycles was solved after one or two attempts by Mr. Fox, but it will be readily understood that the photograph does not depict the foreign body with the striking clearness with which it was viewed by means of the fluorescent screen.

Remarks.—There is obviously a very broad distinction to be drawn between the procedure here described and the exceedingly difficult and unsatisfactory attacks that have been made on the large bronchi through the mediastina. The transpleural method used in this case will certainly be occasionally employed in the future, thanks to the aid the surgeon is now enabled to claim from the skiagraphist, and one can conceive of no more brilliant illustration of the value of radiography in surgery. Other features that appear to me specially noteworthy are: (1) the fact of abscess formation having already commenced; (2) the lobar consolidation subsequent to the operation; and (3) the suppuration of the chest wall without suppuration of the pleura, although the two structures were in widely open communication with one another. Finally, I would venture strongly to urge upon any surgeon who contemplates a procedure of this nature that a little special *tactus eruditus* acquired beforehand in the dead-house will prove invaluable.

Notes by Mr. FOX.—This patient was sent to me for x ray examination by my friend Mr. Bryant on August 27th, 1903. A shawl pin had disappeared in the circumstances detailed in Mr. Russell's account of the case and it was thought that it had been swallowed. Examination by the x rays at once showed this supposition to be incorrect and revealed the shawl pin lying in the left bronchus. It was then over three weeks since its disappearance. As its point was in the trachea near its bifurcation it was thought that it might be possible to remove it through an opening made into the trachea below the isthmus. As the point of such a pin is, however, a very difficult object to be grasped by, and extracted in, the jaws of a pair of forceps I formed the opinion that it might be practicable to use a powerful electro-magnet in the event of forceps failing to extract it. Experimental investigation, however, showed that an electro-magnet of diameter sufficiently small not to occlude seriously under an anæsthetic the small trachea of a boy 12 years old possessed an inadequate magnetic pull unless exerted over a sufficiently large surface of the object to be removed. Now the position of the pin was such that it practically presented its point to the electro-magnet, and the fact that the magnetic lines of force had thus to act upon a point, combined with the limited size of the magnet itself, rendered it impracticable to remove the pin in this way. Experiments carried out with a very large Haab magnet and iron extension pieces suitable for pushing down the trachea to reach the pin proved this to possess no greater power. The idea of utilising an electro-magnet had thus to be abandoned.

It was then determined to endeavour to extract it by the tracheal route by means of ordinary forceps and as Mr. Bryant was leaving Melbourne for a week or two the case was kindly taken in hand by Mr. Russell and admitted to the Alfred Hospital, with the excellent and highly gratifying result recorded. Another x ray examination was then made with this view, when it was found that meantime the pin had found its way so much farther down the bronchus that it had become impracticable to reach and to extract it through a tracheal opening. The pleural route was then determined upon and I was asked to locate exactly the round glass head of the pin. To do this I adopted a method the principle of which is precisely similar to that I advocated in a former issue of THE LANCET[1] and which I have employed on numerous occasions since. It consists of ascertaining the exact position of two straight lines in the same plane intersecting one another at right angles, the point of intersection being occupied by the object to be located. The most suitable plane for these lines to be in is one at right angles to the axial line of the body. This affords the easiest and most useful measurements. This plane is represented in the diagram (Fig. 2), in which A B and C D are the two lines at right angles to each other. The line A B is found by taking two small circular discs of lead and attaching them to the skin by means of fish-glue or some similar material. By means of the x rays and a fluorescent screen these two metal discs are moved about, sliding them on the surface of the skin until the disc at A, the head of the pin at E, and the other disc at B are all in one straight line (A B). Such a line to be in the above-mentioned plane should be, with the patient standing, as nearly as possible a horizontal one. The discs A and B are so placed that A B is a true antero-posterior line. In an exactly similar manner the line C D is mapped out, this being also a horizontal line at right angles to A B and extending from side to side instead of antero-posteriorly. Now F G is a line drawn parallel to A B and passing through C, while G B and F A are each parallel to C E. Now F A = G B = C E, which is the depth the head of the pin E is in the cavity of the thorax from the position of the disc at C. From this it should be quite clear that C (which in this particular case is the nearest point to the object sought) gives the position where the opening into the pleura should be made and the requisite amount of rib in that location excised, while C E (or what is the same thing, G B or F A) gives the depth the operator must go in the direction of D to reach the head of the pin. The collapse of the lung on opening the pleura in this case of course alters the position of the pin in the thorax, but that can scarcely be held to vitiate the method of location.

An attempt to photograph the pin in position was at first a complete failure, no pin showing in the photograph, although it was very plainly visible on the screen. The fault lay in the free movement of the pin with the lung during respiration and by controlling diaphragmatic action and stopping this up-and-down movement a good photograph was at once obtained.

A curious point about this case that should be noted is that the pin fell into the left bronchus and not into the right. It is a well known fact that when a foreign body enters the trachea and falls below its bifurcation it nearly always enters the right bronchus, rarely the left. In the event of no signs or symptoms being present (as in this case) to indicate its position and in the absence of an x ray examination one can easily imagine a surgeon who suspected that it had dropped down the trachea diligently but vainly exploring the right bronchus. The case is altogether an excellent illustration of the immense assistance x ray examination affords in suitable cases to the operating surgeon.

Melbourne.

THE PATHOLOGY AND TREATMENT OF ECLAMPSIA.

BY JOHN W. BYERS, M.A., M.D., M.A.O.
(HON. CAUSÂ) R.U.I.,
PROFESSOR OF MIDWIFERY, QUEEN'S COLLEGE, BELFAST; PHYSICIAN TO THE BELFAST MATERNITY HOSPITAL; PHYSICIAN FOR DISEASES OF WOMEN TO THE ROYAL VICTORIA HOSPITAL, BELFAST; CONSULTING PHYSICIAN TO THE BELFAST HOSPITAL FOR SICK CHILDREN; AND EXAMINER IN OBSTETRIC MEDICINE IN THE ROYAL UNIVERSITY OF IRELAND.

THERE is no more interesting subject in the whole range of obstetric medicine than eclampsia, and yet, despite the recent advances in every department of medical science, our knowledge of convulsions occurring in pregnancy, during labour, and after delivery, is still anything but accurate, defined, or scientific.

THE PATHOLOGY OF ECLAMPSIA.

Two views at present hold the field as to the pathology of eclampsia. 1. Our present position, according to one view, corresponds to that of our predecessors in the last century in reference to dropsy. We call convulsions associated with pregnancy, labour, or the lying-in period eclampsia, but just as in the case of dropsy closer observation and more accurate post-mortem evidence showed that there were several morbid conditions underlying that clinical term, so in the case of eclampsia some believe we have included in it a number of disease entities, each due division of primitive and more diffused single stars. But if this theory is correct we should expect the orbit of a double star to be approximately circular; yet this is so far from being the case that the eccentricity of the orbits of many double stars exceeds by far any of the eccentricities in the solar system. Now See has pointed out that when two bodies of not very unequal masses revolve round one another in close proximity the conditions are such as to make tidal friction as efficient as possible in transforming the orbit. Hence we seem to see in tidal friction the cause which may have sufficed not only to separate the two component stars from one another, but also to render the orbit eccentric. I have thought it best to deal very briefly with stellar astronomy in spite of the importance of the subject because the direction of the changes in progress is in general too vague to admit of the formation of profitable theories.

---

[1] THE LANCET, Sept. 21st, 1901, p. 784.

We have seen that it is possible to trace the solar system back to a primitive nebula with some degree of confidence and that there is reason to believe that the stars in general have originated in the same manner. But such primitive nebulæ stand in as much need of explanation as their stellar offspring. Thus, even if we grant the exact truth of these theories the advance towards an explanation of the universe remains miserably slight. Man is but a microscopic being relatively to astronomical space and he lives on a puny planet circling round a star of inferior rank. Does it not, then, seem as futile to imagine that he can discover the origin and tendency of the universe as to expect a house fly to instruct us as to the theory of the motions of the planets? And yet, so long as he shall last, he will pursue his search, and will no doubt discover many wonderful things which are still hidden. We may, indeed, be amazed at all that man has been able to find out, but the immeasurable magnitude of the undiscovered will throughout all time remain to humble his pride. Our children's children will still be gazing and marvelling at the starry heavens but the riddle will never be read.

REMOVAL OF A LARGE PIN FROM THE LOWER LOBE OF THE LUNG BY TRANSPLEURAL PNEUMOTOMY.

BY R. HAMILTON RUSSELL, F.R.C.S. ENG.,
SURGEON TO THE ALFRED HOSPITAL, MELBOURNE; CONSULTING SURGEON TO THE MELBOURNE HOSPITAL FOR SICK CHILDREN.

With Notes on the Radiographic Methods employed, by WILLIAM R. FOX, L.R.C.S., L.R.C.P. Edin., *Honorary Physician to the Melbourne Benevolent Asylum.*

(*With Illustrative Plate.*)

I HAVE been unable to discover the record of any case in which the chest has been opened in the free manner employed in this instance for the purpose of extracting a foreign body from the lung and I conclude, therefore, that the features of interest that are presented by it are unique in kind. I am indebted for the earlier notes to Mr. H. W. Bryant, under whose care the boy came in the first instance.

The patient, aged 12 years, was admitted into the Alfred Hospital, Melbourne, under my care on Sept. 12th, 1903, with the following history. Five weeks previously he was sitting in a rocking chair holding in his mouth a large black-headed shawl pin, three inches in length, when the chair was suddenly tilted, and in the effort to save himself the pin disappeared down his trachea without any cough or spasm of the glottis. No symptoms of any kind appeared to have supervened until a week later, when he began to be troubled with a cough, and a week later still the sputa became blood-stained. Three weeks after the occurrence he was examined radioscopically by Mr. W. R. Fox, and the pin was seen to be in the left bronchus, the head lying two and a half inches below the bifurcation, the point projecting into the trachea. It was suggested by Mr. Fox that an attempt should be made to extract the pin with an electro-magnet which he undertook to devise and construct, and as it was thought likely that tracheotomy might be required the patient was admitted under my care into the Alfred Hospital. Without going into unnecessary detail it was found at a subsequent examination made by Mr. Fox that the pin had travelled down into the lower lobe of the lung and that all idea of extracting it through the trachea would have to be abandoned. The boy's symptoms on admission were exceedingly slight; there was a little irritative cough and occasionally a streak of blood was expectorated; there was also a slight irregularity of temperature, which sometimes rose to between 99° and 100°F. at night; otherwise he appeared to be in excellent health and careful auscultation revealed nothing.

On radioscopic examination the following points were noted. The pin was readily seen lying in the lower part of the left lung, the point being directed obliquely upwards towards the trachea (Fig. 1). At each cardiac pulsation the point of the pin rose and fell as though it were resting upon the base of the heart. The position of the head could be easily indicated on the chest wall by examining in two positions, antero-posteriorly and laterally, and marking the spot coinciding with the head in either position. It was then found that when viewed antero-posteriorly the head was about on a level with the eighth rib; when viewed laterally it lay in a vertical plane corresponding to that of the posterior fold of the axilla. The project of extracting the pin through an opening in the chest wall looked as though it should be an easy matter; nevertheless it was novel work, and I had reason to be very glad that before undertaking it upon the living I sought an opportunity of studying the matter in the dead-house.

The results of my experimental investigations with a similar pin and a lung removed from the body were as follows. In the first place, it was clear that the pin had passed into the main bronchus of the lower lobe of the lung, which corresponded exactly with the position of the pin as shown by the rays. Secondly, I ascertained that by grasping the lobe firmly between the fingers and thumb and making a slight rocking movement I was able with a little practice to detect the rigidity caused by the presence of th pin. The observation which was really the most importar of all, however, was concerned with the extreme slipperines of the foreign body in the bronchus. I found that havin once grasped the lung containing the pin it would never d to let go or to relax the grasp until the pin was extracted Anything in the nature of fumbling caused the pin to sli away with great readiness and as it would then be travellin point first, the point being, moreover, in close proximit to the great vessels at the base of the heart, the danger that might result from maladroit handling were obvious an very real. Upon these considerations the following operatio was planned and carried out.

Operation (Oct. 2nd).—The boy being placed on his righ side, a free curved incision with the convexity downward was made and the flap thus marked out was reflected upwards. A portion of the left eighth rib six inches long was then removed from the postero-lateral part of the chest and air was cautiously permitted to enter the pleura through a small puncture. The resulting collapse of the lung was not attended by untoward symptoms and the pleura was opened up to the full extent of the wound. Ample room was afforded; the fingers of the left hand were passed between the lung and the diaphragm, the lower lobe grasped near its root and gently drawn towards the opening. It was now possible to recognise the rigidity caused by the presence of the pin. Maintaining a firm hold with the left hand the position of the head of the pin was ascertained by gently palpating the surface of the lung with the right fingers. A small incision was made in the lung over the pin's head; a sinus forceps, unopened, was pushed in until the pin was felt and by hitching the instrument under the neck of the pin the head was easily lifted out of the wound and the pin was withdrawn. There was no hæmorrhage but it is a notable circumstance that abscess formation had already begun round the foreign body, for when the head of the pin was reached a small quantity of pus (10 or 20 minims) escaped. No suture was put into the very small wound in the lung. The flap of integument was replaced and sutured with the exception of about two inches in the middle. This was left unclosed by sutures and a piece of oiled silk protective was laid over it before the dressings were applied; by this means free escape of air from the pleura was insured, while the piece of protective by its valvular action would impede the passage of air back into the pleura and thus encourage the expansion of the lung. Immediately after the operation there was great restlessness, which was relieved by a small dose of morphine, and for two or three days there were some dyspnœa and general distress, which, however, steadily diminished. There was also moderate fever, the temperature ranging between 99° and 100°, and examination of the chest revealed very mixed with butter and placed upon the back of the tongue may be administered. If the patient is unconscious the following is the plan now pursued at the Rotunda Hospital. I quote from the last report of Mr. E. Hastings Tweedy, the master: "We pass a stomach-tube through the mouth in the event of our patient being deeply unconscious and through the nose if she be in a state of semi-consciousness. In the former condition the soft palate fails to respond to the stimulation of the nose tube and the latter is in consequence much more likely to be passed into the trachea than through the œsophagus. By means of this tube the stomach is thoroughly washed out. Into the stomach is then poured, by means of the tube, a quart of slightly saline hot water, together with castor oil, elaterin, croton oil in four or five drop doses, or some saline purgative, according to the predilection of the operator." During the past ten years I have abandoned the use of chloral and chloroform for the convulsions and used instead morphine on the plan suggested originally by G. Veit. I give half a grain of morphine hypodermically when the fits commence followed by one-quarter grain doses as often as is found necessary to control the fits, the idea being simply *to keep the convulsions* in check. I have given two grains in this way in a period of 24 hours. Of course, each case must be watched carefully, and smaller amounts of the morphine will do in some cases than in others, but I feel that, owing to the teaching in reference to the use of morphine in Bright's disease, many medical men are afraid to use morphine so freely as it may be used in eclampsia. Very often a grain is all that is needed in divided doses to stop the fits. The great advantage of morphine over chloroform for the treatment of the fits is that it does not depress the heart. According to some authorities, another benefit of morphine is that while it is being administered it arrests metabolism. At the same time the patient's bowels are also evacuated by frequent enemata of soap and water with *castor oil*. Saline enemata may also be given but I prefer the subcutaneous injection, under the breasts, of saline solution. I have tried bleeding with the subsequent injection of the saline solution directly into the veins but do not think the results better than those following the subcutaneous injection into the areolar tissue. I have entirely abandoned the use of pilocarpin but I have seen benefit follow the use of the hot pack, though the present teaching of the Rotunda is against either it or any diaphoretic.

2. *Methods of eliminating the poison.*—This is best done by free purgation either by the mouth or by enemata, by saline infusion, by the hot pack, and by the non-administration of liquids.

3. *The obstetric management of eclampsia.*—Here we at once find recommended among obstetricians the most opposite lines of practice. The present teaching in the Rotunda is reverting to the view held by the older obstetricians, who advised treating the convulsions and letting the labour alone. In his last report (for 1903-4) the present master of the Rotunda writes: "Labour is never induced, nor is its onset to be desired. Should it unfortunately occur its progress is seldom interfered with. In the one case in which we departed from this rule the convulsions seemed to be rather aggravated than diminished by the complete delivery." On the other hand, Dührssen, and still later Bumm, as well as Leopold, profess by immediate delivery to have obtained good results, the method being mainly forcible dilatation of the cervix by incisions or dilators followed by emptying of the uterus as soon as it can be done after the onset of the fits. What line of practice is to be recommended with such contradictory advice? One thing is clear: no one but an expert obstetric operator who is accustomed to do abdominal and vaginal gynæcological work could attempt to try, as a routine practice in every case, the immediate emptying of the uterus, and even according to statistics the results seem better with the morphine plan. My own method is as follows:—When the convulsions occur in pregnancy, labour not having set in, I give the morphine, with purgation, and saline infusion and let the patient alone obstetrically. If, however, labour has set in I think it should be shortened by forceps under chloroform when the cervix indicates that this can safely be done. Suppose, however, that in spite of the morphine treatment the patient gets steadily worse, then I think we are justified in terminating the labour by emptying the uterus, using Bossi's dilator, followed by forceps or any other method that can be employed, acting as in the case of any patient whose state seems to indicate that the labour should be terminated with as little delay and as little disturbance as possible.

4. *Prophylaxis of eclampsia.*—In a pregnant woman we fear the onset of eclampsia when the principal eliminating organs—the kidneys—are not acting properly, this being evidenced by albuminuria and diminution in the amount of urine and urea excreted. Even before such premonitory symptoms as headache, giddiness, disturbance of vision, or severe epigastric pain have set in, we should endeavour to ward off an attack of convulsions. The patient, clothed in flannel, should be kept in bed, have a warm bath every night, and a free action of the bowels every day (cream of tartar, compound senna mixture, or compound powder of jalap may be given). She should be kept mainly on a milk diet with vegetables, bread-and-butter, and stewed fruit, and have plenty of fluids, plain water and mineral waters, to drink. If this plan is thoroughly carried out most cases will not develop convulsions.

While every case of eclampsia must be treated *per se*, I would recommend the following methods if the attack cannot be warded off:—

1. Treat the convulsions with morphine used subcutaneously. Keep the patient on her side, purge freely in the method recommended, use saline infusion, allow no liquids; in a word, as Gooch advised long ago, "take care of the convulsions, and let the uterus take care of itself."
2. Make an effort to eliminate the poison by purgation, hot packs, and by saline infusion.
3. If labour has not set in treat the convulsions but do not induce premature action of the uterus. If labour has begun and the patient is in the second stage and the os dilated give chloroform and deliver by forceps if possible, or by turning. If, however, morphine and purgation with saline injections have been tried and the patient is not improving, dilate the cervix and deliver.
4. For the convulsions after delivery use morphine, purgatives, and saline infusion.
5. In the prophylaxis of eclampsia rest, milk diet, warm baths, and purgatives are the best methods.

Belfast.

A CASE OF TUMOUR OF THE CAUDA EQUINA REMOVED BY OPERATION, WITH REMARKS ON THE DIAGNOSIS AND NATURE OF LESIONS IN THAT SITUATION.

By W. B. WARRINGTON, M.D. LOND., F.R.C.P. LOND.,
PHYSICIAN TO THE DAVID LEWIS NORTHERN HOSPITAL; LECTURER IN NEURO-PATHOLOGY IN THE UNIVERSITY OF LIVERPOOL.

THE twelfth dorsal spinous process and the space below it are opposite the sacral segments of the spinal cord and thus the origin of important nerves is located within a very small extent of nervous matter. From this fact, and since the central nervous system is incapable of regeneration, injury or disease to this part readily causes a maximum amount of destruction and little can be expected from surgical or, indeed, other forms of treatment. The great leash of nerve roots forming the cauda equina arising from the lumbar and sacral segments of the cord occupies, on the contrary, a long vertical extent and the pathological processes affecting the roots often only cause a partial, and if capable of removal, a recoverable form of injury. Hence surgical interference which is easy may also be attended with very considerable and even complete success. The symptoms are necessarily very similar whether the lesion is in the nerves or in the spinal medulla from which they take their origin.

Injury and disease in these two situations are not infrequent and it is therefore of much practical importance to be able to say whether the site of the morbid condition is in the cord (the conus medullaris) or in the cauda equina. I relate first a case of tumour implicating and limited to the cauda equina and afterwards give some account of the diagnosis and nature of the lesions met with in these situations.

I am much indebted to Dr. John Owen, the medical tutor to a different pathological lesion. The old view—that eclampsia depends on poisoning of the nerve centres by certain by-products which the kidney, owing to its abnormal condition, fails to eliminate—is now practically abandoned; indeed, if one special pathological condition is to be admitted as connected with eclampsia it would not be a lesion of the kidney but rather of the liver. At the Congress of Obstetrics and Gynecology in 1896, at Geneva, I saw for the first time microscopic sections exhibiting changes in the liver cells associated with eclampsia. These were shown by Professor Lindfors of Upsala. Bouffe de Saint Blaise, in his "Thèse de Paris, 1891, 'Lésions anat. que l'on trouve dans l'Éclampsie," tells us he found hepatic lesions in 42 consecutive cases and Schmorl[1] discovered them in 71 out of 73 necropsies. J. Whitridge Williams in his text-book of obstetrics says he has been able to demonstrate similar lesions in all the eclamptic livers examined by him, and he gives a figure showing that these hepatic lesions consist in irregularly-shaped red or white areas of necrosis caused by degenerative changes following thrombosis of the smaller portal vessels. All agree that in eclampsia the main post-mortem lesions are in the kidney, liver, and the brain, and while pathologists at present tell us that of these changes the most characteristic are in the liver, there is a doubt whether such morbid conditions are primary or secondary: the majority of observers hold that nearly all post-mortem changes in eclampsia are secondary. 2. The second view is that eclampsia depends upon a poison, a toxin or series of toxins manufactured by the mother and fœtus, and that the various changes found post mortem are really caused by the over-accumulation and non-elimination of these toxins. Now it must at once be admitted that no one has hitherto been able to isolate any of these toxins which may be said to be the specific cause of eclampsia. For the present the "toxæmia" view is the popular one, and while it may be accepted provisionally as a good working hypothesis and while there is considerable clinical and post-mortem evidence to support this view, it must be candidly admitted that scientific proof of the existence of the specific causation of eclampsia is still wanting. We are making progress by showing that older theories have become untenable, and, perhaps, in the future, as the result of combined clinical, chemical, and laboratory investigation, we may find a solution of a most interesting and engrossing problem. For the present, Zweifel's dictum still holds that eclampsia is "the disease of theories."

Certain points in the etiology of eclampsia must, however, be borne in mind by those who are seeking for an explanation of the condition which will cover all the facts.

1. Why is eclampsia so common in primiparæ and especially among those who are young or old? My own experience bears out Professor Schauta's statistics that there are nearly five times as many cases among primiparæ as among multiparæ. As to age, Dührssen, out of 195 cases of eclampsia, found 40·5 per cent. were either below 20 or over 30 years of age. To say, as an explanation of the fact, that primiparæ are more liable to eclampsia than multiparæ that their nervous system is more impressionable, and that pregnancy brings out any flaw in their constitution, is a mere begging of the question.

2. Why is eclampsia commoner in certain districts than in others? In the recent discussion on Dr. Robert Boxall's paper on the Treatment of Albuminuria and Eclampsia occurring in Pregnancy, which was read at the Leicester meeting of the British Medical Association, Dr. O. E. Purslow of Birmingham said he had only three cases of eclampsia in 6400 labours. As the general death-rate from puerperal convulsions was 0·3 per mille for Birmingham, his own district must be comparatively immune. At the Rotunda Hospital there were 56 cases of eclampsia among 20,000 patients, a proportion of 1 in 357. When collecting statistics for a paper read at the 1896 International Congress of Obstetrics and Gynæcology at Geneva I was much struck with the fact that certain parts of the United Kingdom had in a marked degree more cases of eclampsia than other districts. Does any other complication of pregnancy show such a remarkable variation in its occurence in some parts of the country more than in others?

3. Why is eclampsia commoner in certain years? Is this a mere coincidence and would such observations be different if we made records throughout longer periods, say fifty years instead of five or ten?

4. A most important point in the etiology of eclampsia is the part played by the fœtus. It is surely a very remarkable circumstance, to which attention was first drawn by the late Professor Winckel, that when, during pregnancy, the fœtus dies, even in the case of a woman who has what we term the premonitory symptoms of eclampsia, the danger for her is entirely overcome or very much diminished. Many years ago, before I was aware of Winckel's observation, I was much struck with this fact. I was asked to see a young primipara with the idea of bringing on labour. She was in the eighth month of pregnancy and had for a week been suffering with severe headache and occasional vomiting. The urine had been gradually diminishing and two days before I saw her it was when examined by her medical attendant, almost solid on boiling. There was œdema of the face and limbs. At our consultation the patient said that for the past day and night she had been unable to feel the child's movements and neither her own medical man nor I could hear the fœtal heart, nor could we discover the active movements of the fœtus. We decided to induce labour, but the patient was anxious that her mother should be with her and so we decided not to interfere until the next day when her mother was present. On the next day the patient said she felt better, the œdema was diminished, the urine had increased and was less albuminous, and under these circumstances we decided to wait. The patient steadily improved and a week later, after a natural labour, gave birth to a dead fœtus whose skin was peeling. All albumen had now disappeared. She has since had three living children and no return of any of the symptoms as observed in her first pregnancy. I have seen since several similar cases and I called special attention to this point at the Geneva congress in a paper introducing the question of the treatment of eclampsia. In the discussion which followed Professor Morisani (Naples) and Professor Pasquali (Rome) took part. The former stated that before deciding on obstetrical intervention it was necessary to ascertain whether the child was alive or dead, as he had on several occasions proved that the death of the fœtus put an end to the convulsions and the albuminuria. Professor Pasquali said he had found that the death of the child checked the eclampsia, and he confirmed the view put forward by me by stating that this fact suggested the question whether the fœtus does not play a rôle in the etiology of such a dangerous complication.

As further evidence in support of the view that the fœtus is an important factor in the rôle of the causation of eclampsia I may mention the following two points. In twin pregnancy there is a greater risk of eclampsia; statistics showed that while there is one twin pregnancy to 13 normal pregnancies in eclampsia there was only one twin pregnancy to 80 in pregnant women generally. Two French observers, Baron and Castaigne,[2] have shown that the transmission to the mother of substances injected into the fœtus ceases almost immediately after its death.

THE TREATMENT OF ECLAMPSIA.

For the sake of clearness, and accepting the toxin view as a working hypothesis, we may consider the treatment of eclampsia under the following heads:—1. How can the convulsions be treated? 2. How is the poison which is assumed to cause the fits to be eliminated? 3. What is the best way to manage the patient from an obstetric point of view? 4. When certain symptoms set in which make us fear the occurrence of eclampsia, what is the best treatment to adopt?

1. *Treatment of the convulsions.*—The patient, the subject of eclampsia, should be placed on her side (not on her back) with the head low. In this way fluids from the mouth do not tend to get into the larynx or lungs and so we try to avoid one of the morbid conditions so often seen in fatal cases of eclampsia—œdema of the lungs. The handle of a toothbrush or of a spoon covered with linen should be placed between the teeth at the first indication of an approaching fit to prevent injury to the tongue. A cork is sometimes used but it should never be employed because with the patient's movements small pieces may be bitten off and carried into the air-passages. If the patient is conscious a rapidly acting purgative such as five grains of calomel, a drachm of compound powder of jalap, or a drop of croton oil

---

[2] Contribution à l'Etude de la Pathogénie de l'Eclampsie Puerpérale, etc., Archives de Médecine Expérimentale et d'Anatomie Pathologique, 1898.

mixed with butter and placed upon the back of the tongue may be administered. If the patient is unconscious the following is the plan now pursued at the Rotunda Hospital. I quote from the last report of Mr. E. Hastings Tweedy, the master: "We pass a stomach-tube through the mouth in the event of our patient being deeply unconscious and through the nose if she be in a state of semi-consciousness. In the former condition the soft palate fails to respond to the stimulation of the nose tube and the latter is in consequence much more likely to be passed into the trachea than through the œsophagus. By means of this tube the stomach is thoroughly washed out. Into the stomach is then poured, by means of the tube, a quart of slightly saline hot water, together with castor oil, elaterin, croton oil in four or five drop doses, or some saline purgative, according to the predilection of the operator." During the past ten years I have abandoned the use of chloral and chloroform for the convulsions and used instead morphine on the plan suggested originally by G. Veit. I give half a grain of morphine hypodermically when the fits commence followed by one-quarter grain doses as often *as is found necessary to* control the fits, the idea being simply to keep the convulsions in check. I have given two grains in this way in a period of 24 hours. Of course, each case must be watched carefully, and smaller amounts of the morphine will do in some cases than in others, but I feel that, owing to the teaching in reference to the use of morphine in Bright's disease, many medical men are afraid to use morphine so freely as it may be used in eclampsia. Very often a grain is all that is needed in divided doses to stop the fits. The great advantage of morphine over chloroform for the treatment of the fits is that it does not depress the heart. According to some authorities, another benefit of morphine is that while it is being administered it arrests metabolism. At the same time the patient's bowels are also evacuated by frequent enemata of soap and water with castor oil. Saline enemata may also be given but I prefer the subcutaneous injection, under the breasts, of saline solution. I have tried bleeding with the subsequent injection of the saline solution directly into the veins but do not think the results better than those following the subcutaneous injection into the areolar tissue. I have entirely abandoned the use of pilocarpin but I have seen benefit follow the use of the hot pack, though the present teaching of the Rotunda is against either it or any diaphoretic.

2. *Methods of eliminating the poison.*—This is best done by free purgation either by the mouth or by enemata, by saline infusion, by the hot pack, and by the non-administration of liquids.

3. *The obstetric management of eclampsia.*—Here we at once find recommended among obstetricians the most opposite lines of practice. The present teaching in the Rotunda is reverting to the view held by the older obstetricians, who advised treating the convulsions and letting the labour alone. In his last report (for 1903-4) the present master of the Rotunda writes: "Labour is *never* induced, nor is its onset to be desired. Should it unfortunately occur its progress is seldom interfered with. In the one case in which we departed from this rule the convulsions seemed to be rather aggravated than diminished by the complete delivery." On the other hand, Dührssen, and still later Bumm, as well as Leopold, profess by immediate delivery to have obtained good results, the method being mainly forcible dilatation of the cervix by incisions or dilators followed by emptying of the uterus as soon as it can be done after the onset of the fits. What line of practice is to be recommended with such contradictory advice? One thing is clear: no one but an expert obstetric operator who is accustomed to do abdominal and vaginal gynæcological work could attempt to try, as a routine practice in every case, the immediate emptying of the uterus, and even according to statistics the results seem better with the morphine plan. My own method is as follows:—When the convulsions occur in pregnancy, labour not having set in, I give the morphine, with purgation, and saline infusion and let the patient alone obstetrically. If, however, labour has set in I think it should be shortened by forceps under chloroform when the cervix indicates that this can safely be done. Suppose, however, that in spite of the morphine treatment the patient gets steadily worse, then I think we are justified in terminating the labour by emptying the uterus, using Bossi's dilator, followed by forceps or any other method that can be employed, acting as in the case of any patient whose state seems to indicate that the labour should be terminated with as little delay and as little disturbance as possible.

4. *Prophylaxis of eclampsia.*—In a pregnant woman we fear the onset of eclampsia when the principal eliminating organs—the kidneys—are not acting properly, this being evidenced by albuminuria and diminution in the amount of urine and urea excreted. Even before such premonitory symptoms as headache, giddiness, disturbance of vision, or severe epigastric pain have set in, we should endeavour to ward off an attack of convulsions. The patient, clothed in flannel, should be kept in bed, have a warm bath every night, and a free action of the bowels every day (cream of tartar, compound senna mixture, or compound powder of jalap may be given). She should be kept mainly on a milk diet with vegetables, bread-and-butter, and stewed fruit, and have plenty of fluids, plain water and mineral waters, to drink. If this plan is thoroughly carried out most cases will not develop convulsions.

While every case of eclampsia must be treated *per se*, I would recommend the following methods if the attack *cannot be warded off*:—

1. Treat the convulsions with morphine used subcutaneously. Keep the patient on her side, purge freely in the method recommended, use saline infusion, allow no liquids; in a word, as Gooch advised long ago, "take care of the convulsions, and let the uterus take care of itself."

2. Make an effort to eliminate the poison by purgation, hot packs, and by saline infusion.

3. If labour has not set in treat the convulsions but do not induce premature action of the uterus. If labour has begun and the patient is in the second stage and the os dilated give chloroform and deliver by forceps if possible, or by turning. If, however, morphine and purgation with saline injections have been tried and the patient is not improving, dilate the cervix and deliver.

4. For the convulsions after delivery use morphine, purgatives, and saline infusion.

5. In the prophylaxis of eclampsia rest, milk diet, warm baths, and purgatives are the best methods.

Belfast.

A CASE OF TUMOUR OF THE CAUDA EQUINA REMOVED BY OPERATION, WITH REMARKS ON THE DIAGNOSIS AND NATURE OF LESIONS IN THAT SITUATION.

BY W. B. WARRINGTON, M.D. LOND., F.R.C.P. LOND.,
PHYSICIAN TO THE DAVID LEWIS NORTHERN HOSPITAL; LECTURER IN NEURO-PATHOLOGY IN THE UNIVERSITY OF LIVERPOOL.

THE twelfth dorsal spinous process and the space below it are opposite the sacral segments of the spinal cord and thus the origin of important nerves is located within a very small extent of nervous matter. From this fact, and since the central nervous system is incapable of regeneration, injury or disease to this part readily causes a maximum amount of destruction and little can be expected from surgical or, indeed, other forms of treatment. The great leash of nerve roots forming the cauda equina arising from the lumbar and sacral segments of the cord occupies, on the contrary, a long vertical extent and the pathological processes affecting the roots often only cause a partial, and if capable of removal, a recoverable form of injury. Hence surgical interference which is easy may also be attended with very considerable and even complete success. The symptoms are necessarily very similar whether the lesion is in the nerves or in the spinal medulla from which they take their origin.

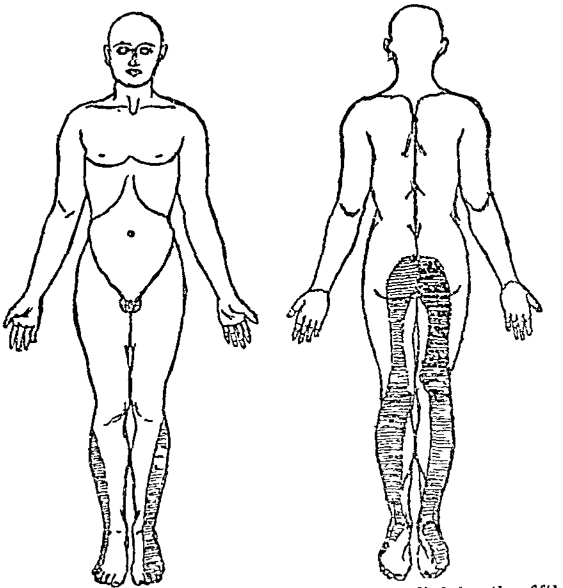
Injury and disease in these two situations are not infrequent and it is therefore of much practical importance to be able to say whether the site of the morbid condition is in the cord (the conus medullaris) or in the cauda equina. I relate first a case of tumour implicating and limited to the cauda equina and afterwards give some account of the diagnosis and nature of the lesions met with in these situations.

I am much indebted to Dr. John Owen, the medical tutor at the hospital, for many careful notes on the condition of the patient.

The patient, a laundryman, aged 36 years, was admitted to hospital on August 4th, 1904, on account of pain in both thighs and weakness of the lower limbs. He had suffered from the pain for about five months; the loss of power had developed later. Four years ago he contracted gonorrhœa followed by stricture of the urethra. On one occasion retention of urine had to be relieved by suprapubic puncture. Beyond this no history of illness could be elicited. Syphilis was denied and there was no evidence of it. The father had died from a "tumour of the brain" at the age of 56 years. The mother, three brothers, and five sisters are living and in good health. The patient looked ill and worn and evidently suffered greatly; he was anæmic and somewhat emaciated. He weighed 9 stones 4 pounds. The heart and lungs were normal. Nothing could be detected on palpation of the abdomen or by digital examination of the rectum. The urine was of specific gravity 1016; it contained no albumin or sugar.

The following is a description of the symptoms present. There was severe, spontaneous, shooting pain, often worse at night. It started about the middle line at the level of the highest part of the sacrum, passed downwards over both buttocks and the posterior surface of the thighs and outside of the legs as far as the ankle, but did not invade the feet. The pain was much worse when he lay on either side or on the face and was then referred especially to the lower part of the sacrum. There was sharp pain on flexing the thigh on the pelvis (sign of Lasègue), but no particular pain on pressing the muscles of the thigh or legs or along the course of the great sciatic nerve or at the points of Valleix.[1] The first, second, and third lumbar spines were somewhat uniformly prominent; no pain was caused by percussing these or by vertical pressure or by lateral pressure through the iliac crests. There was, however, considerable rigidity of the lower part of the spine. In bending backwards, forwards, or laterally, whilst the upper part of the spine moved the lower portion remained immobile and the resulting movement was one of the trunk together with the pelvis on the thighs. There were considerable loss of power in both lower limbs, more markedly so on the left side, inability to raise the left thigh against the least resistance, and weakness in the flexors of the leg and the thigh and in the muscles moving the feet, though none of these movements were absolutely paralysed. Thus there seemed to be weakness in all the muscles supplied by the lumbo-sacral plexus. All the muscles reacted to the faradic current but to a less extent on the left side. The knee-jerks were both brisk but the ankle-jerks were absent. The plantar reflexes were present though difficult to elicit. At times the reflex was a quick extensor reflex and at others the flexor type predominated. Micturition was normal but the patient stated that he had not as good control over the action of the bowels as formerly; he had to go to stool quickly in order to avoid soiling himself. On examining the rectum digitally the sphincter ani contracted fairly forcibly on to the finger and the rectum appeared to be dilated and ballooned. The patient also stated that he did not feel the examination. There was marked loss of sensation to touch and pain in the areas figured on the chart (Fig. 1). Light touches with the blunt head of a pin were not recognised at all and a pin prick was recognised as a dull, just perceptible sensation. This anæsthesia invaded, as figured, the penis, scrotum, and perineum. As regards the sexual organs, testicular sensation was preserved but there had been neither erections nor emissions for six months.

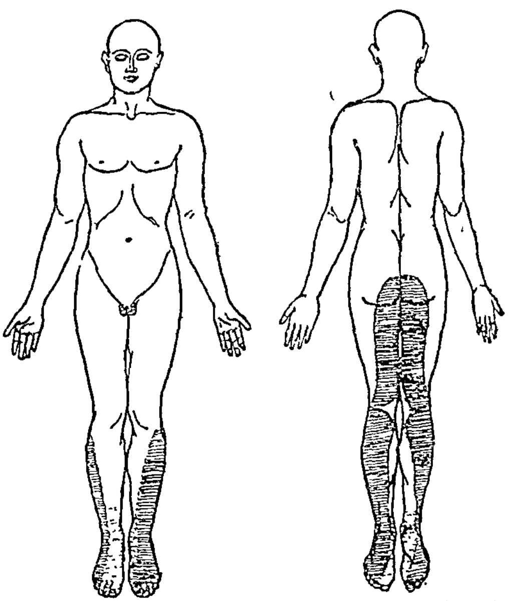
FIG. 1.



August 17th. Loss of sensation in the areas supplied by the fifth lumbar and all the sacral roots.

In the course of a fortnight the symptoms were considerably more defined and permitted an accurate analysis to be made. The motor weakness was bilateral, rather more on the left than on the right side. There was great increase in the weakness of the movement of the feet, which soon became absolutely powerless. On the other hand, the extensors of the legs—the quadriceps group—and the extensors and external rotators of the thighs, though somewhat weaker than natural, acted with moderate force, so that the leg could be raised from the bed. Abduction of the thighs was well performed. The biceps femoris was felt to contract but feebly. The semitendinosus and semimembranosus also contracted and apparently not with greatly diminished force. The muscles of the legs were somewhat but not greatly wasted. There was no reaction of degeneration, though the faradic irritability was diminished in all the leg muscles. The ankle-jerks remained absent; the plantar reflex could not now be obtained. The left jerk had gradually diminished and on August 29th it was absent. The right knee-jerk was brisk and on tapping the quadriceps tendon a lively contraction of the adductors on both sides occurred. The abdominal and cremastic reflexes were brisk. On the 23rd the patient first complained of some *difficulty* in passing urine, stating that he had to strain. Retention set in a few days *later* necessitating the use of a *catheter*, which the patient was unable to feel. Enemata were required; there were also involuntary passage of fæces and *total loss* of sensation of the act. The anus was patulous. The inner sides of the legs were now becoming anæsthetic (see *Fig.* 2), the area of loss of sensation in this zone being fairly well defined and more marked for pain than for touch. *The pain* remained very severe, necessitating the continual administration of morphine.

FIG. 2.



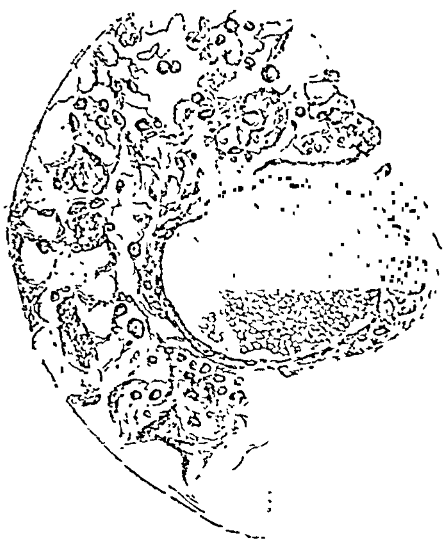
August 29th. The anæsthesia appeared in the fourth lumbar area.

---

[1] Those places along the course of nerves which in neuralgia are painful on pressure.

The diagnosis of tumour of the cauda equina was made and an operation was performed by my colleague, Mr R. W. Murray, on Sept. 2nd. The spines and laminæ of the second, third, and fourth lumbar vertebræ were removed. On opening the dura mater a red, soft looking mass about an inch long was seen surrounded by the nerve roots. It bled very readily when the attempt to remove it was made but a considerable portion was removed. Subsequent examination showed the tumour to be an endothelioma or hæmorrhagic angiosarcoma (see Fig. 3). Rather unexpectedly the patient improved considerably and regained the power of walking with the aid of sticks, the knee-jerks returned, and the anæsthesia greatly diminished, but the state of the bladder and rectum did not improve. The pain also was very much relieved. Unfortunately at about the end of three months symptoms began to return and pain became again very severe. There could be little doubt from the histological examination that the tumour was malignant and that it had rapidly grown again.

FIG. 3.



Microscopical appearance of section of growth removed.

A second operation was thought to offer some slight chance of further relief, but on exposing the nerves it was found that the tumour had grown enormously and was now from two to three inches long. As the condition was obviously incurable Mr. Murray and I considered it justifiable to divide a number of posterior roots. The patient remained till death completely paralysed in the lower limbs and shortly after the operation pain, which had eased for a time, returned with great severity.

Remarks on the nature and diagnosis of diseases in this situation.—The distribution of the roots, forming respectively the lumbar and sacral plexuses, is now fairly well agreed upon. The lumbar roots form the anterior crural and obturator nerves and supply the quadriceps extensor group and the adductors of the thigh; their sensory distribution is on the front and sides of the thigh and inner side of the leg. It is obvious that in the case of my patient the functions of these nerves were unimpaired and that the lesion was one interfering with the functions of the sacral plexus. Such an extensive bilateral affection, nearly symmetrical, could be explained only by a lesion of these nerves, either where they are situated close together forming the cauda equina, or by implication of their centres of origin in the lowest part of the cord itself—viz., the conus medullaris. This term has been arbitrarily fixed to include that part of the cord which lies between the origin of the second and third sacral nerves to its termination, a definition which is convenient, since injury limited to it implies either a total or partial integrity of the lumbar nerves and, further, since it is a clinical fact that lesions of the cauda equina invade chiefly the sacral roots. Anatomically, indeed, the cauda equina includes the great leash of nerve roots which form both the lumbar and sacral plexuses, but for the reasons just mentioned its use clinically is restricted to the roots forming the sacral plexus.

A table given by Raymond,[2] constructed from clinical data, shows precisely the distribution according to that author of the last lumbar and first five sacral segments of the cord or the corresponding roots (see table). With regard to the sensory areas given in this table, I prefer to accept the scheme given by Seiffer,[3] made from a comparison of the many clinical observations on this subject, and place his statements adjoining Raymond's table. These areas are very much in agreement with those recorded in a valuable paper by Dr. C. R Box,[4] who has described the symptoms produced by a tumour of the cauda equina, in which the fifth lumbar roots were the first affected, producing anæsthesia on the outer side of the leg, the dorsum, and most of the sole of the foot; thence the growth of the lesion produced symptoms indicating invasion of one root after another in both an upward and a downward direction. In the case of my patient the anæsthesia involved all the areas of the sacral and the fifth lumbar roots, whilst the muscles belonging to the upper roots were not much affected. At a later period the appearance first of anæsthesia of the inner side of the leg and then of the loss of knee-jerks showed that the fourth and third lumbar roots were being invaded by the growth.

Raymond's Table.				*Sensory Supply according to Seiffer.*
—	Motor.	Sensory.	Reflexes.	
5th L. (abd.)	Glut. med and min., tens. fasc. femoris, semimemb., semitend., biceps.	Outer side of thigh.	—	Ext. surface of leg, dorsum of foot, sole of foot.
1st S. (ext. rot.)	Pyriformis, obt. internus, gemelli, glut. max.	Posterior surface of thigh and leg.	Plantar.	Ext. surf. of leg, dorsum and sole of foot; outer part of posterior surface of leg.
2nd S.	Tib. ant., peroneal muscles, centre for erection.	External surface of leg and of foot, sensation of bladder and upper part of rectum.	—	Median part of posterior surface of thigh.
3rd S.	Centre of ejaculation, ischio- and bulbo-cavernosi.	Sensation of urethra, penis, and scrotum.	—	Penis, scrotum, vulva, perineum, and region of buttocks.
4th S.	Muscles of bladder.	Perineum, sacral region.	Ankle jerk.	An oval area including the region of sacrum as far as the anus.
5th S.	Levator ani. sphincter ani.	Coccygeal region, anus.	Anal.	—

The diagnostic problems were: 1. Is the lesion in the cord (the conus medullaris) or the cauda equina? 2. What is its nature? The symptoms must necessarily be very similar, since the muscular paralysis, sensory disturbance, and affection of the bladder or rectum may be equally produced by a nuclear (spinal cord) or radicular lesion. It is therefore only by a consideration of the collateral circumstances that a diagnosis can be made. Excluding for the present external injury as a cause, the writings of Raymond[5] and Sippy[6] indicate the following points as being in favour of a lesion of the roots. 1. An insidious onset with general development and progression of symptoms. The conus medullaris gives origin from a very small extent to many nerves and hence a lesion primarily affecting it would rapidly produce its maximum amount of damage. 2. Pain, violent in nature, spontaneous or excited by change of position or by movement, is in favour of a radicular lesion; moderate pain may be present in either condition. 3. Pain over the vertebral column below the level of the second lumbar spine, exaggerated by percussion and radiating towards the lower limbs, is in favour of a lesion of the cauda equina. To this I am inclined to add rigidity of the lower part of the spine due to irritation of the nerves of the dura mater. Pain higher up, increased by pressure and not radiating very clearly over the lower limbs, is in favour of a medullary lesion. The sign of Lasègue (pain on flexing the thigh with the leg extended on to the pelvis), though it may be absent, is a further indication of a radicular lesion. 4. An asymmetrical development is a radicular symptom and is perhaps especially suggestive of an extradural lesion; remission of symptoms, especially amelioration in the condition of the bladder and rectum, and the slow appearance of muscular wasting, of the reaction of degeneration, and of trophic disturbance are also in favour of an affection of the cauda equina.

[6] Journal of Nervous and Mental Diseases, p. 108, 1902.

The symptoms produced by disease or injury in either of these situations on the bladder, rectum, and external organs of generation are important. We know chiefly from the work of Langley and Anderson that these organs receive a double innervation, one from the lower dorsal and upper lumbar roots through their white rami to the sympathetic and the other from the pelvic splanchnic or nervus erigens from the sacral roots. The exact functions of these two sets of fibres is not certainly known, but clinically an affection of the conus medullaris or its roots is attended by both motor and sensory paralysis of the bladder and rectum. This was so in the case recorded by Osler[7] in which a syphilitic gummatous process was limited to the third, fourth, and fifth anterior and second and third posterior sacral roots. Erection of the penis is also usually absent in these lesions. Hence the sacral centre is the more important. Raymond remarks and indicates in his table that the nerves of sensation are given off from a higher part of the cord than those of the muscles of the bladder and rectum; hence the two forms of paralysis are not always associated, as in one of the cases quoted by Raymond where there was incontinence of urine without any anæsthesia. The reverse condition was present in a case recorded by van Gehuchten[8] of damage to the conus in which with complete control over the sphincters and with the urine voided in a nearly natural manner the mucous membrane of the urethra and bladder was absolutely anæsthetic. Van Gehuchten,[9] indeed, draws the inference from this case that the sympathetic ganglia can function quite independently of the central nervous system. But it may be that in such a case the activity of the lumbar centre is sufficient. More difficult to explain is the fact that erections of the penis also occurred, although this organ was absolutely anæsthetic and presumably the sacral centre had been completely destroyed. The acts of ejaculation of semen and forcible expulsion of the last few drops of urine depend on the contraction of the bulbo- and ischio-cavernosi muscles and are always paralysed if the lowest sacral part of the cord or the corresponding roots are damaged; hence van Gehuchten concludes that it is only with unimpaired capacity for these actions and in the persistence of the anal reflex that the diagnosis of integrity of the conus medullaris and the corresponding roots can be made.

Nature of lesions of the cauda equina.—Dufour in his work, "Contribution à l'Étude des Lésions des Nerfs de la Queue du Cheval du Cone Terminal," in 1896 collected and analysed nearly 100 cases of lesions of the cauda equina, the great majority of these being traumatic; next in frequency came tumours, then forms of meningitis with or without hæmorrhage, tubercle, and syphilis.

Trauma.—Injury limited to the cauda equina is rare; usually the terminal part of the cord is also implicated. The site of the lesion is of much importance. Van Gehuchten,[10] who has analysed Dufour's cases, gives the following conclusions: 1. If no injury of the vertebral column is found it is probable that the medulla spinalis will have been injured. 2. In injuries of the first lumbar vertebra or above the conus medullaris is alone affected. 3. Injury to the second lumbar vertebra may cause damage to either the cone or the cauda equina, since the level at which the cord terminates varies; in lesions at this site injury to the cone cannot be excluded. 4. Injury below this level causes damage to the cauda equina.

Tumours.—These may take origin from the bones or meninges, from the cord or nerves, and may be extra- or intra-dural. Sarcoma and carcinoma seem the varieties most frequently met with, but fibrosarcoma, neuromata, glioma, lymphangioma, and myolipoma have been found. Dufour collected 21 cases; in only one had an operation been performed and this was successful (Laquer and Rehn). Since then several cases of very successful removal have been recorded—two cases of extradural sarcoma by Sachs[11] and an extradural endothelioma by A. Starr.[12] A further case operated upon is recorded by Frankel.[13] The patient died two months later after some temporary improvement. The tumour was a red pultaceous mass, microscopically a sarcoma. Putnam and Elliot[14] relate a case of extradural carcinoma which was removed. The patient also died in about five months, probably from a growth in the brain. This tumour, however, attacked the lower part of the cord rather than the cauda and as it could not be completely removed and the pain was agonising two nerve roots on each side were deliberately divided. The authors remark: "It might be justifiable to divide the cord above the new growth, so imperative was the need of relieving the extreme suffering." At a meeting of the Neurological Society on Oct. 27th, 1904, Dr. Ferrier and Sir Victor Horsley showed a patient from whom a fibromyxoma comprising the conus and cauda equina had been removed with marked success.

The diagnosis of tumour can only be made from the history, usually a considerable duration, and the progressive uninterrupted march in the severity of symptoms. At times, as in my case, the progress may be very rapid, a feature, of course, depending on the nature of the growth.

Hydatid cyst.—All the eight cases collected by Dufour occurred in women; in one the tumour presented as a fluctuating mass through the laminæ and another is noticeable on account of a remarkable remission of symptoms. In one many cysts invaded the central nervous system.

Meningitis and neuritis.—Under this head are cases of varying pathology. Only a few have been recorded; undoubted instances of syphilitic gummatous meningitis have been recorded by Osler and Westphal. This part of the nervous system may also be invaded by tubercle. Dr. Ferrier and Mr. Ballance showed a patient in whom this condition had been treated by operation with much success. Pachymeningitis hypertrophica occurred in one case amongst those collected by Dufour. The thickening of the membrane invaded the dura mater over the lumbar enlargement as well as over the cauda equina.

Lastly three recent cases of unilateral lesion of the cauda equina recorded by Raymond[15] may be abstracted.

CASE 1.—A patient, aged 46 years, whose occupation, that of a washerwoman, required her to stand for long periods of time and to be constantly working in cold water, began to suffer from pain in the lumbar region on the left side, which ameliorated somewhat during the next year. One morning on waking she found her left leg paralysed and flaccid. For several days there were also constipation and retention of urine. The bladder symptoms improved a little but four months later, on admission to hospital, she was found to have a bedsore on the left side of the sacrum with the paralysis and a distribution of anæsthesia met with in lesions of the sacral roots. The symptoms were throughout unilateral. Raymond considers the case to be one of a chronic meningitis. He rejects the diagnosis of tumour on account of the history, intermittent progress of symptoms, and the rather sudden onset of paralysis.

CASE 2.—A woman, aged 28 years, by occupation a machinist, was rather suddenly taken with violent pains in the middle of the sacral region radiating along the thighs in the course of the sciatic nerves, more severe in the left than the right side. Later, difficulty in walking developed with the characteristic paralysis of motion and sensation, but much more marked in the left side. There was no pain on pressure over the course of the sciatic nerve or at the points of Valleix. The sign of Lasègue was absent. There was incontinence of urine which later disappeared, and the sensation of the bladder and rectum was not interfered with. A trophic sore developed over the sacrum. The ankle-jerks and anal reflex were absent. The duration was two years. Raymond makes the diagnosis of radicular neuritis, caused by the occupation of the patient, the history and transitory improvement being against a tumour.

CASE 3.—The patient, a man, aged 38 years, a coachman and a hard drinker, suffered from numbness and tingling in the lower limbs, and a week later, after continuous exposure to rain, noticed that he had suddenly lost power in the left foot. The weakness gradually invaded the leg and thigh; there was also considerable pain in those parts; later difficulty in micturition occurred, followed, however, by a return to the normal condition. In this condition, having been ill 15 days, he went to hospital. He was found to have the characteristic motor and sensory paralysis in the left side with the reaction of degeneration in the muscles of the leg. The knee-jerk was present; the ankle-jerk was absent. There was no pain on pressure over the course of the sciatic nerve and the sign of Lasègue was absent. There was no anal reflex and he could not dislodge the last drops of urine from the urethra without much straining. Although he had no incontinence of urine or fæces yet the mucous membranes were insensitive. Raymond again considers this case to be one of radicular neuritis. The sudden onset indicates that it is in part a vascular lesion, an apoplectiform neuritis, but not comparable to those cases in which a hæmorrhage takes place into the sheath of the nerves; in such instances the symptoms attain their maximum extent at once and then gradually diminish or at least remain stationary. Raymond rather considers it is a form of compression, a pachymeningitis hæmorrhagica. The diagnosis of tumour was rejected on account of (1) the unilateral nature of the symptoms; (2) the rapid onset; and (3) the temporary amelioration.

PS.—The patient in my case died early last May. At the necropsy the original growth was found to be of very large size and multiple growths were present in the pia mater along the whole length of the spinal cord. A similar growth was also present in the angle formed by the cerebellum, pons, and medulla.

Liverpool.

129 CONSECUTIVE AND SUCCESSFUL OPERATIONS FOR APPENDICITIS DURING THE QUIESCENT PERIOD IN 12 YEARS (TREVES'S OPERATION).[1]

BY J. LYNN THOMAS, C.B., F.R.C.S. ENG.,

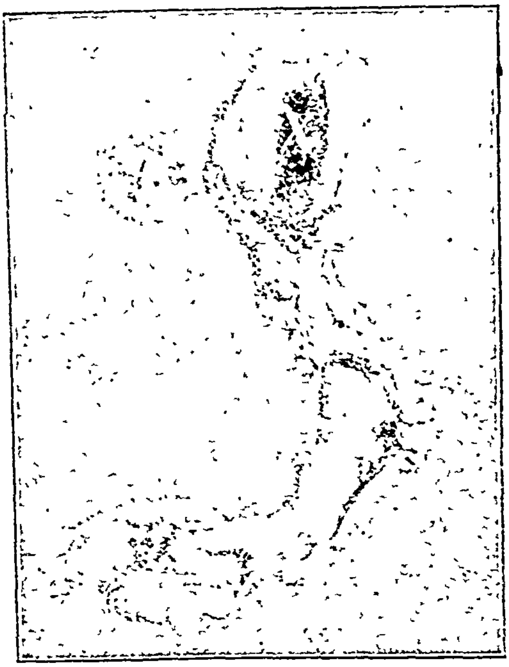
SURGEON TO THE CARDIFF INFIRMARY; CONSULTING SURGEON TO THE HAMADRYAD HOSPITAL, PORTH HOSPITAL, BRIDGEND COTTAGE HOSPITAL, CARDIFF PROVIDENT DISPENSARY, AND BARRY ACCIDENT HOSPITAL.

MY first operation was performed on April 17th, 1893, on a patient of Dr. J. D. Williams. It was done in so small a room that the anæsthetist had to take his position on the bed which occupied most of the available space. The appendix was retrocæcal in position and about two inches of the right ureter and the common iliac blood-vessels were exposed before it was successfully removed. It was an ordeal for a beginner. My first seven patients belonged to seven different nationalities, an extraordinary illustration of the universality of the disease.

Up to the year 1898 operations were performed under the wet antiseptic system; since then they have been performed under dry aseptic methods, the operator and the assistants wearing thread gloves regularly. Sponges were discarded with the antiseptic method and gauze was substituted. The change from the antiseptic to the aseptic method has left two lasting impressions upon my mind: the first is that shock or reaction after operation is very much less under aseptic methods, due in some degree to the fact that the patient's system is not poisoned by the absorption of carbolic acid or perchloride of mercury: and the second is the disappearance of suppuration and stitch abscess. When these complications occur the surgeon or his assistants are usually at fault, but occasionally one finds a patient who has coarse and rough skin, or is liable to eczema or other forms of dermatitis from trivial causes: but even in such patients suppuration can be prevented by taking the sutures out within 24 hours and by paying special care to the skin. When pus appears in a clean wound the surgeon's technique is at fault. The abdominal wound was closed by *en masse* sutures during the antiseptic system and in tiers since it was discarded. The number of layers of buried sutures varies with the thickness of the abdominal wall. When the stratum of subcutaneous fat exceeds half an inch its surfaces are approximated by buried sutures in order to leave as little tension as possible upon the skin sutures. During the antiseptic period layers of iodoform or cyanide gauze were placed next the skin and then the whole of the abdomen was covered with Gamgee tissue and kept in place by a broad bandage and a spica round the right thigh. At present no bandages or other dressings are used as the wound is simply sealed with gauze and collodion dressing. Formerly patients were kept in bed for from two to four weeks; now they are allowed to get up in from 8 to 13 days after operation. Nevertheless it is necessary to caution patients against doing stupid things when they get away from the surgeon's control. One of my patients took a hot bath and went for a long drive on a cold day on the twelfth day after appendicectomy; he was punished by a severe attack of pneumonia.

I advise removal of the appendix in cases (*a*) of operation for ventral hernia following the opening of a perityphlitic abscess; (*b*) in cases of persistent thickening or induration after a first attack of appendicitis (see Fig. 1). Occasionally I have removed the appendix after the first attack has run a normal course, owing to the patient's dread of having another attack when travelling in places where experienced surgeons would not be available. Lastly, I advise removal of the appendix after two definite inflammatory attacks. It is incumbent on all good surgeons to emphasise the condition *inflammatory*, as quite a host of healthy appendices have been removed for so-called appendicular colic. There can be no doubt but that there are definite attacks of appendicular colic due to circumstances similar to those which give rise to renal and biliary colic; nevertheless I think one should be extremely careful in estimating the value of this particular symptom in forming an opinion as to the advisability of having an operation performed. There is another sign—tenderness over McBurney's point—which often misleads like a will-o'-the-wisp, if the surgeon looks upon it as a valuable symptom. It is present in many other conditions than that of appendicitis. Quite recently I saw two patients who had had appendicectomy performed for the combined symptoms of "apyrexial appendicular colic with well-marked tenderness over McBurney's point" without the slightest benefit to the unfortunate victims. Those who have strong faith in the value of these symptoms would do well to ponder over Dr. Johnson's notion about the wind egg. If the clinician takes the trouble to test for tenderness over McBurney's point in cases where there is no suggestion of appendicitis he will perhaps be surprised to find it "well marked" in a certain number of apparently healthy

FIG. 1.



Appendix removed for a first attack. The concretion marked 1, removed from X, must have existed many months before the symptoms of peritonitis set in.

---

[1] A paper read before the Medical Society, Newport (Mon.), on April 18th, 1905.

individuals; also in cases of right renal colic, early caries of the spine, Glénard's disease, colitis, and dilated stomach, &c.

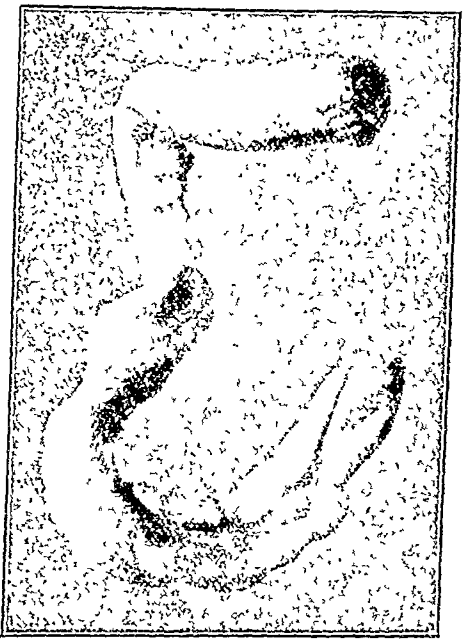
In connexion with the difficulties of forming a correct diagnosis I would like to refer to a remarkable case that I saw in 1899 with Dr. C. C. Shepherd. A man, aged about 30 years, had had between 60 and 70 definite attacks of appendicular colic, accompanied by vomiting and well-marked tenderness over McBurney's point lasting from a few hours to two or three days. There was no hæmaturia or albuminuria. We deferred interfering with the appendix until we observed a complete attack. The next one was of exceptional severity and came on whilst the patient was walking. He was found insensible and collapsed and his life was despaired of for a time but he gradually recovered with his "usual symptoms of appendicitis," but a swelling was noticed behind the cæcum which extended to the right loin, suggesting nephritic or perinephritic trouble. I operated and removed a large clot of blood from around a small cystic kidney with a short impermeable ureter which terminated in a cord. The condition of the kidney was evidently congenital and the probable explanation of the repeated attacks of simulated appendicitis was due to small recurrent hæmorrhage round the cystic kidney, but until the last attack they were not of sufficient volume to give rise to a detectable swelling. The patient has enjoyed excellent health since the operation (1904).

I may further illustrate the difficulties and pitfalls which diagnosticians have to face in cases of simulation of appendicitis by recording the following examples:—

CASE 1. *Salpingitis simulating enteric fever.*—A woman, who was on a visit to Cardiff, was treated as a case of typhoid fever and was sent to the sanatorium, where for a time the disease seemed to run the course of ordinary enteric fever until a swelling appeared in the right iliac fossa. Dr. D. R. Paterson saw her in consultation with Dr. E. Walford. The symptoms now pointed to the development of a perityphlitic abscess. I was asked to see her and concurred with the diagnosis. At the operation it turned out to be a case of right salpingitis due to acute infection by the gonococcus. Some months afterwards when applying to the London Truss Society the patient reported herself as a case of operation for perforation during an attack of enteric fever!

CASE 2. *Persistent biliary colic simulated by concretions in misplaced appendix.*—A man, aged 50 years, was taken into the Cardiff Infirmary for treatment as a case of biliary colic. Recurring and sudden nauseating pains over the site of the gall-bladder made the patient unsuited for work. I agreed with the diagnosis and treated him accordingly. I opened the abdomen over the gall-bladder by Kocher's oblique incision and removed a nine-inch convoluted appendix with concretions in it (Fig. 2). The cæcum had not descended to its usual position but remained in contact with the gall-bladder. The gall-bladder was distended. I opened it in order to make certain of its contents. It was healthy and contained no calculi and the patient has had no further trouble from colic.

FIG. 2.



Appendix which gave rise to colic simulating passage of gall-stones owing to undescended cæcum.

When the cæcum in its developmental evolution does not descend to its normal anatomical position appendicitis in these circumstances simulates diseases of viscera in that particular region. In one case I operated for perforation of a supposed duodenal ulcer but was surprised to find that it was a case of gangrenous appendicitis with perforation near its attachment to the cæcum which lay in contact with the under surface of the liver.

In women it is frequently difficult to make a correct diagnosis between inflammation of the right ovary and right Fallopian tube and that of the vermiform appendix. Sometimes they are all simultaneously involved in the process. In perforative appendicitis the symptoms are in the early stages not uncommonly identical with rupture of a right tubal pregnancy, but fortunately in these conditions proper treatment does not depend upon correct pre-operative differential diagnosis but upon the adoption of means to meet the conditions found after the abdomen is opened in cases where perforation is diagnosed.

When a case presents a definite swelling near or in the pelvis and there is a doubt as to its being due to blood, serum, or pus, an examination of the blood for leucocytosis is of considerable importance, but in deciding upon the urgency of operating it is necessary to bear in mind that big collections of pus in an appendix or a Fallopian tube are capable of being removed by non-operative natural processes. *Ubi pus ibi incisio* is an excellent law for observation in practice but it is not to be taken as that of the Medes and Persians "which altereth not." I saw a female patient with Mr. J. P. T. Burke at Llanbradach during the third week of an attack of suppurative appendicitis. She stated that she had had a similar attack some years ago and that she got well by the "discharge of much matter" through the vagina. She had a globular swelling occupying the right half of the pelvis and extending upwards as high as the right anterior superior iliac spine. Her temperature was 103° F. and her pulse was 102. She had had rigors and sweatings; per vaginam the swelling was fluctuating. An operation was advised and on the next day she was driven to Cardiff Infirmary, but owing to a sudden fall in her pulse-rate and temperature I kept her under observation for nearly a month and the swelling gradually got smaller until it reached to less than a quarter of its size on admission. At the operation I removed the appendix and the whole track of the abscess cavity; the appendix had ulcerated through its coats near its base into the meso-appendix and formed an abscess cavity which became attached to, and perforated, the anterior abdominal wall; its contents had become dried up into firm putty-like material.

In my list of cases I only operated once during pregnancy for relapsing appendicitis during the sixth to seventh month at the infirmary. The appendix was carried upwards by the uterus and the operation was easy and done quickly and the patient had a normal recovery and went to term.

Amongst the unusual complications of relapsing appendicitis was one of glycosuria. A female patient of Dr. R. H. S. Torney, Cowbridge, was kept under observation for about a month before I operated. The glycosuria was intermittent and large quantities of sugar were sometimes passed. After I removed a tensely distended appendix there was no recurrence of glycosuria. The appendix was filled with bluish-white pus having a foul, nauseating smell. Unfortunately it was put at once into formalin. The pus in all probability contained poison with properties similar to those possessed by phloridzin, which under the varying tension that it was subjected to in the appendix periodically became absorbed and gave rise to glycosuria.

Mr. Llewellyn C. P. Phillips of Cairo, in an interesting paper upon Some of the Surgical Aspects of Glycosuria and Diabetes,[2] has collected four cases of appendicitis associated with glycosuria. The treatment in three of his cases was expectant and in the fourth an abscess was opened. In my case removal of the appendix with its offensive contents cured the glycosuria promptly.

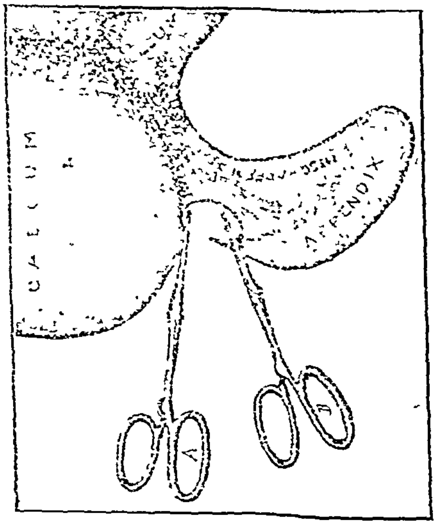
---

[2] THE LANCET, May 10th, 1902, p. 1309, Table I.

In three cases I did not remove the whole of the appendix owing to the risk involved; in two the tip of the appendix was incorporated with the rectum wall and I left the end implanted in the rectum; in one convalescence was protracted but eventually the patient became free from pelvic pain and has remained so for more than two years. In three cases I did not attempt to remove the appendix as it was surrounded by coils of small intestine so densely bound together that successful removal would have involved resection of intestine and a perilous dissection of the mass in order to liberate it from the sacrum and brim of the pelvis. In one of these patients an abscess subsequently formed which discharged into the rectum and was cured; the other two patients enjoy good health but for an occasional "bout of indigestion." I think it is better to let nature deal with such conditions than to perform dangerous and hazardous operations for which patients are not prepared. Patients prefer to put up with life in discomfort than to die victims to ultra-radical operations.

There is no royal road either as to the method of opening the abdomen or of removing the appendix, but in a large number of cases one can amputate the appendix through a two-inch skin incision and forcible entry by blunt dissection through the muscular planes but it often becomes necessary to enlarge the opening considerably in order to deal with unforeseen complications. Sometimes the complete operation can be performed with ease in ten minutes but usually it takes more than double that time and the last one I did (April 13th, 1905) took one and a half hours. The Trendelenburg position is of great value in cases where the appendix is situated in the pelvis; in these cases it is usually easier to remove the appendix by starting from above by severing it from the cæcum and then continue the dissection downwards towards the tip. I adopt the same course in cases where there is no meso-appendix and where the end of the appendix is tied down. This method is also preferable in cases where the base of the appendix is healthy and its end has a pear-shaped enlargement (see Fig. 3). In all other conditions of the appendix it is easier to start at the free end and work towards its attachment to the cæcum. On occasions where the diseased appendix resembles an icicle in relation to its attachment to the cæcum it is occasionally necessary to remove a small piece of the cæcal wall in order to get a suitable stump. It has not been my fortune in most of the cases to be able to perform an ideally simple method of dealing with the stump of the appendix—i.e., crush it at its cæcal attachment and apply two pairs of narrow-bladed forceps to the crushed part and either burn off or cut off along the forceps attached to the cæcum, then tie and invaginate by either a purse-string or interrupted suture. I find a serrated crushing forceps far superior to a smooth one owing to its obliterating effect upon the blood-vessels.

FIG. 3.



To show that when the appendix is in the pelvis, or has no meso-appendix, the first step is to crush its attachment to the cæcum and to apply two pairs of forceps to the crushed part which is then cauterised or cut flush along forceps A.

No matter what method is used in treating the stump it is not only desirable but always necessary to bring the peritoneum over raw surfaces whenever possible, as post-operative complications in after years can only be avoided by careful attention to these details. A patient who was operated upon by a well known surgeon in 1890 and to whom I administered the anæsthetic died last year from acute strangulation due to a coil of intestine being incarcerated under a band extending from the end of the cæcum to the abdominal wall. The base of the appendix was simply tied and cut off after the early fashion of dealing with an ovarian pedicle. When the stump cannot be covered with the peritoneum the end of the cæcum can usually be fixed to the abdominal wall by points of sutures or omental flaps applied to it.

In cases of retrocæcal position of the appendix great care should always be taken to close accurately by suture the incision made through the peritoneum for its exposure, as a complication occurred within 12 months of appendicectomy in one of my cases which I am not aware of having been previously recorded. In February, 1900, I removed a retrocæcal appendix containing pus and I allowed the cæcum to fall back into its natural position after the operation. In time the patient began to lose flesh and complained of dragging pain in the region of his stomach. He consulted Sir Lauder Brunton and was advised to undergo operation in order to deal with some mechanical obstruction to the passage of food from the stomach. I operated and found that the great omentum had got fixed into the retrocæcal space made for the removal of the appendix. I divided the great omentum, which dragged upon the transverse colon and stomach, and the patient was kept lying on his left side for some days after operation in order that the divided surfaces of the omentum should be kept well apart during the process of repair. Since that experience I carefully close all incisions made in the peritoneum and if drainage of the retrocæcal space is thought advisable it can be done extraperitoneally by extending the parietal incision upwards and backwards parallel with the crest of the ilium and an inch above it.

Cardiff.

FAMILY TABES DORSALIS: TABES IN HUSBAND, WIFE, AND DAUGHTER.[1]

BY E. F. TREVELYAN, M.D., B.Sc. LOND.,
F.R.C.P. LOND.,
PHYSICIAN (WITH CHARGE OF OUT-PATIENTS) TO THE LEEDS GENERAL INFIRMARY.

IN 1898 I recorded an instance of conjugal tabes dorsalis[2] of which the main details were as follows. The man, aged 58 years, married at 22 years of age and showed early symptoms of tabes at the age of 33 years. In 1898 the pupils did not react to light and the knee-jerks were absent. There was marked incoördination in the legs in consequence of which he was bedridden. There were characteristic pains and bladder symptoms. He had had a passing hemiplegia a year previously. The woman, aged 55 years, married at 19 years of age and developed the early symptoms of tabes at the age of 29 years. In 1898 the pupils were very small and did not react to light. She suffered from pains, attacks of vomiting, and bladder symptoms. The left tibia had fractured spontaneously and both knees were swollen from tabetic arthropathy. The question of past syphilis could not be thoroughly investigated in this tabetic couple, but the family history (to be given later) and the occurrence of the tabes itself made syphilis practically certain.

Since the date mentioned above the man has died, aged 58 years. The wife remains in much the same state, the disease being almost, if not quite, stationary. She has occasional pains and bladder symptoms, but she is able to earn money by sewing. The eldest daughter now presents well-marked symptoms of tabes. In 1898 I strongly suspected that she was commencing with the disease owing to individuals; also in cases of right renal colic, early caries of the spine, Glénard's disease, colitis, and dilated stomach, &c.

---

[1] A paper read before the Neurological Society on May 18th, 1905.

[2] Trevelyan: Brit. Med. Jour., vol. ii., 1898.

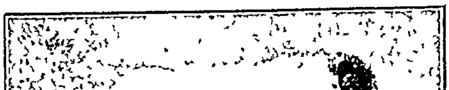
In connexion with the difficulties of forming a correct diagnosis I would like to refer to a remarkable case that I saw in 1899 with Dr. C. C. Shepherd. A man, aged about 30 years, had had between 60 and 70 definite attacks of appendicular colic, accompanied by vomiting and well-marked tenderness over McBurney's point lasting from a few hours to two or three days. There was no hæmaturia or albuminuria. We deferred interfering with the appendix until we observed a complete attack. The next one was of exceptional severity and came on whilst the patient was walking. He was found insensible and collapsed and his life was despaired of for a time but he gradually recovered with his "usual symptoms of appendicitis," but a swelling was noticed behind the cæcum which extended to the right loin, suggesting nephritic or perinephritic trouble. I operated and removed a large clot of blood from around a small cystic kidney with a short impermeable ureter which terminated in a cord. The condition of the kidney was evidently congenital and the probable explanation of the repeated attacks of simulated appendicitis was due to small recurrent hæmorrhage round the cystic kidney, but until the last attack they were not of sufficient volume to give rise to a detectable swelling. The patient has enjoyed excellent health since the operation (1904).

I may further illustrate the difficulties and pitfalls which diagnosticians have to face in cases of simulation of appendicitis by recording the following examples:—

CASE 1. *Salpingitis simulating enteric fever.*—A woman, who was on a visit to Cardiff, was treated as a case of typhoid fever and was sent to the sanatorium, where for a time the disease seemed to run the course of ordinary enteric fever until a swelling appeared in the right iliac fossa. Dr. D. R. Paterson saw her in consultation with Dr. E. Walford. The symptoms now pointed to the development of a perityphlitic abscess. I was asked to see her and concurred with the diagnosis. At the operation it turned out to be a case of right salpingitis due to acute infection by the gonococcus. Some months afterwards when applying to the London Truss Society the patient reported herself as a case of operation for perforation during an attack of enteric fever!

CASE 2. *Persistent biliary colic simulated by concretions in misplaced appendix.*—A man, aged 50 years, was taken into the Cardiff Infirmary for treatment as a case of biliary colic. Recurring and sudden nauseating pains over the site of the gall-bladder made the patient unsuited for work. I agreed with the diagnosis and treated him accordingly. I opened the abdomen over the gall-bladder by Kocher's oblique incision and removed a nine-inch convoluted appendix with concretions in it (Fig. 2). The cæcum had not descended to its usual position but remained in contact with the gall-bladder. The gall-bladder was distended. I opened it in order to make certain of its contents. It was healthy and contained no calculi and the patient has had no further trouble from colic.

FIG. 2.



Appendix which gave rise to colic simulating passage of gall-stones owing to undescended cæcum.

When the cæcum in its developmental evolution does not descend to its normal anatomical position appendicitis in these circumstances simulates diseases of viscera in that particular region. In one case I operated for perforation of a supposed duodenal ulcer but was surprised to find that it was a case of gangrenous appendicitis with perforation near its attachment to the cæcum which lay in contact with the under surface of the liver.

In women it is frequently difficult to make a correct diagnosis between inflammation of the right ovary and right Fallopian tube and that of the vermiform appendix. Sometimes they are all simultaneously involved in the process. In perforative appendicitis the symptoms are in the early stages not uncommonly identical with rupture of a right tubal pregnancy, but fortunately in these conditions proper treatment does not depend upon correct pre-operative differential diagnosis but upon the adoption of means to meet the conditions found after the abdomen is opened in cases where perforation is diagnosed.

When a case presents a definite swelling near or in the pelvis and there is a doubt as to its being due to blood, serum, or pus, an examination of the blood for leucocytosis is of considerable importance, but in deciding upon the urgency of operating it is necessary to bear in mind that big collections of pus in an appendix or a Fallopian tube are capable of being removed by non-operative natural processes. *Ubi pus ibi incisio* is an excellent law for observation in practice but it is not to be taken as that of the Medes and Persians "which altereth not." I saw a female patient with Mr. J. P. T. Burke at Llanbradach during the third week of an attack of suppurative appendicitis. She stated that she had had a similar attack some years ago and that she got well by the "discharge of much matter" through the vagina. She had a globular swelling occupying the right half of the pelvis and extending upwards as high as the right anterior superior iliac spine. Her temperature was 103° F. and her pulse was 102. She had had rigors and sweatings; per vaginam the swelling was fluctuating. An operation was advised and on the next day she was driven to Cardiff Infirmary, but owing to a sudden fall in her pulse-rate and temperature I kept her under observation for nearly a month and the swelling gradually got smaller until it reached to less than a quarter of its size on admission. At the operation I removed the appendix and the whole track of the abscess cavity; the appendix had ulcerated through its coats near its base into the meso-appendix and formed an abscess cavity which became attached to, and perforated, the anterior abdominal wall; its contents had become dried up into firm putty-like material.

In my list of cases I only operated once during pregnancy for relapsing appendicitis during the sixth to seventh month at the infirmary. The appendix was carried upwards by the uterus and the operation was easy and done quickly and the patient had a normal recovery and went to term.

FAMILY TABES DORSALIS: TABES IN HUSBAND, WIFE, AND DAUGHTER.[1]

BY E. F. TREVELYAN, M.D., B.SC. LOND.,
F.R.C.P. LOND.,
PHYSICIAN (WITH CHARGE OF OUT-PATIENTS) TO THE LEEDS GENERAL INFIRMARY.

IN 1898 I recorded an instance of conjugal tabes dorsalis[2] of which the main details were as follows. The man, aged 58 years, married at 22 years of age and showed early symptoms of tabes at the age of 33 years. In 1898 the pupils did not react to light and the knee-jerks were absent. There was marked incoördination in the legs in consequence of which he was bedridden. There were characteristic pains and bladder symptoms. He had had a passing hemiplegia a year previously. The woman, aged 55 years, married at 19 years of age and developed the early symptoms of tabes at the age of 29 years. In 1898 the pupils were very small and did not react to light. She suffered from pains, attacks of vomiting, and bladder symptoms. The left tibia had fractured spontaneously and both knees were swollen from tabetic arthropathy. The question of past syphilis could not be thoroughly investigated in this tabetic couple, but the family history (to be given later) and the occurrence of the tabes itself made syphilis practically certain.

Since the date mentioned above the man has died, aged 58 years. The wife remains in much the same state, the disease being almost, if not quite, stationary. She has occasional pains and bladder symptoms, but she is able to earn money by sewing. The eldest daughter now presents well marked symptoms of tabes. In 1898 I strongly suspected that she was commencing with the disease owing to

---

[1] A paper read before the Neurological Society on May 18th, 1905.

[2] Trevelyan: Brit. Med. Jour., vol. ii., 1898.

couple developed tabes in her thirty-seventh year—a late date for tabes to develop on a congenital syphilitic basis. It is also true that we found no marks of congenital syphilis upon her and there is only the evidence provided by her family in favour of congenital syphilis.

It is not, however, absolutely necessary for the purpose in question that the patient should bear the usual stigmata of congenital syphilis—indeed, some go so far as to look upon the tabes itself as a stigma of late hereditary syphilis—and on the other hand, I think we have fairly excluded acquired syphilis. It is interesting to note that in the case of a tabetic woman, aged 22 years, bearing the stigmata of congenital syphilis, Barthelemy[30] deliberately assigns the tabes to congenital syphilis although the patient had been abundantly exposed to the infection of acquired syphilis but had not had any of its usual manifestations. Quite apart from the subject of tabetic couples and their offspring, a fair number of cases are on record in which adult tabes has been attributed to congenital syphilis. Usually the disease has commenced before 20 years of age but in some cases considerably later. Thus Max Nonne[31] quotes a case of tabes in a man aged 32 years, who had suffered from severe lightning pains for two years and who had never been infected with syphilis or addicted to drink. The patient had previously been treated for congenital syphilis and Nonne looks upon the latter as the cause of the tabes in this case. Sabrazes[32] has also reported a most interesting case n a man, aged 42 years, in whom the tabes appeared two years previously. In the absence of a history of acquired syphilis and in the presence of marked stigmata of congenital syphilis the author assigns the latter as the cause of the tabes. Pourreyon[33] in his interesting thesis concludes that when tabes or general paralysis is of congenital syphilitic origin it begins at an age between five and 40 years and he adds that these cases are interesting for the study of precocious or late congenital syphilis. Dydynski[34] even goes so far as to say that if observers do not lose sight of congenital syphilis fewer cases of tabes will be recorded where syphilis has been excluded.

The question, it seems to me, may be put in this form in my cases. Did the tabetic couple merely hand down to their daughter a general vulnerability of nervous tissue to certain noxæ (whether in the form of the syphilitic virus or of stress, strain, &c.), or did they transmit to her the actual virus which would bring about with little or no further provocation the eventual degeneration of the afferent sensory neuron?—and I should answer it in the latter sense. Kahlischer[35] has related an instance of tabes in mother and son, the tabes appearing at the age of 26 years in the latter He excludes to his satisfaction both congenital and acquired syphilis and he attributes the tabes almost solely to congenital hereditary influences. This question of neuropathic heredity in tabes (and general paralysis), at one time much emphasised by the French school, is no longer looked upon as of any very great importance. Yet there have been series of cases recorded where the neuropathic heredity has been marked. Thus Berbez[36] as long ago as 1887 mentioned that among 150 cases of tabes there was a neuropathic heredity in 63 and tabes or general paralysis in a parent in 15 of these cases. Dydynski[37] in 1890, in speaking of infantile tabes (and at that time he would only allow seven such cases), found besides congenital syphilis a neuropathic heredity in six. Probably this neuropathic heredity can only mean a greater vulnerability of the nervous system to the causes of tabes such as the syphilitic virus. It is well seen in cases where, for instance, brothers infected with syphilis from different sources (Erb, Max Nonne, and others) have developed tabes. Among my cases I have records of two brothers, one of whom was suffering from tabes when the other developed an acute general paralysis with fits and died within the year. Apart from this vulnerability of the nervous system, it should, no doubt, be remembered that the syphilitic virus may sometimes be of great potency so far as the nervous system is concerned. This is well exemplified when two or more individuals contract syphilis from the same source as in the cases of Erb,[38] Max Nonne,[39] and Marie et Bernard,[40] and all, or nearly all, ultimately develop tabes (or general paralysis), or again in the truly appalling instance related by Brosius[41] where out of seven glass-blowers infected with syphilis from the same source one developed tabes, another tabo-paralysis, and two others general paralysis. As far as the neuropathic heredity is concerned it would appear to be correct to look upon it with Fehre[42] as nothing more than a predisposing cause and probably not as a very important one.

I have to thank Dr. P. G. Steele, the resident medical officer at the Leeds General Infirmary, and Dr. B. Suggit of the Leeds Public Dispensary for assistance in getting together notes and histories of my cases.

Leeds.

A SIMPLE TECHNIQUE FOR THE BACTERIOSCOPIC EXAMINATION OF SEWAGE.

BY W. H. C. FORSTER, M.B., C.M. EDIN.,
D.P.H. CANTAB.,
CAPTAIN, I.M.S.

(From the Laboratory of the Pasteur Institute of India, Kasauli.)

FROM the point of view of the laboratory worker in the East the methods at present in vogue for the quantitative estimation of the "organisms of indication" in sewage leave much to be desired. These methods all presuppose the ice packing of samples when necessary and the existence of a laboratory well stocked with the particular apparatus required—preliminary conditions which do not often obtain in India. Thus it has come to pass that although biological methods for the treatment of sewage have been making steady headway in India for some years past, official and public records are silent on the bacteriological side of the question. It will, I think, be readily admitted that, in the interests of the public health, every biological method for the disposal of sewage should be made the subject of systematic bacterioscopic examination. It is unlikely, however, that this will ever be the case whilst our present methods of investigation remain unaltered. A brief survey of some of the methods at present employed in the bacterioscopic examination of sewage will serve to make the point clear. The criteria usually adopted in the examination of sewage are four in number: (1) the total number of organisms per cubic centimetre; (2) the number of bacillus coli per cubic centimetre; (3) the number of streptococci per cubic centimetre; and (4) the number of spores of bacillus enteritidis sporogenes per cubic centimetre. For the purpose of demonstrating the cumbersomeness of the methods of estimation usually employed it will be sufficient if we indicate only those available for the quantitative estimation of bacillus coli and the spores of bacillus enteritidis sporogenes.

The methods of estimating bacillus coli.—1. By the microscopic examination of colonies developing from surface cultivations on phenolated gelatine or agar plates. These cultivations are made either directly from the material to be examined or from preliminary phenol broth cultures. This method is extremely laborious and even in the most practised hands leaves much to be desired in the way of accuracy. 2. By the neutral-red broth method. 3. By MacConkey's method. 4. By Pakes's method. 5. By Houston's method.

Method of estimating the spores of bacillus enteritidis sporogenes.—The only practicable method is by the use of milk cultures heated to 80° C. for 15 minutes and incubated anaerobically at 37° C.

Whichever method of enumerating bacillus coli the routine worker may adopt he has to face the difficulties of ice packing and apparatus. For example, let us suppose that a sewage-disposal system consisting of an open septic tank and a couple of continuous filters is the subject of the presence of pains. Since then I have watched the pupil reflex gradually (but with variations) diminish and disappear, and also the knee-jerks become less and eventually go altogether, the left disappearing first. The following are the clinical details of this case.

The patient, aged 43 years, commenced to have pains and occasional double vision when she was 36 years of age. She also complained of some difficulty in getting up and down stairs. A feeling of constriction round the body was noticed a little later and occasionally she had slight bladder disturbance. Present condition (May, 1905). The patient is distinctly neurotic but otherwise there are no mental symptoms. The pupils are small (one and a half millimetres) and equal but they do not react to light. A perceptible reaction occurs to accommodation. There is no affection of the eye muscles, no optic atrophy, and no choroiditis. There is some incoordination in the legs, especially in the left, and she sways a little when standing with the eyes closed and the feet together, but this incoördination is very slight. There is a zone of hyperæsthesia round the trunk on a level with the eighth and ninth dorsal vertebræ. There is no knee or tendo Achillis jerk. The plantar reflex is flexor in type. There is no bladder disturbance at the present time.

The family history of this tabetic couple is of considerable interest. There have been 12 pregnancies and of nine children born alive only one was a boy. Only three of these children are still living. The following is an account of the results of the 12 pregnancies: 1. A girl, now aged 43 years (tabetic); married (for family see later). 2. A boy, died, aged 15 years, from rheumatic fever and cardiac disease. 3. A girl, now aged 38 years, quite well; married: ten children (nine living, three miscarriages). 4. A girl, died, aged 14 months. 5. A girl, died, aged 23 years, from puerperal fever. She also had rheumatism and heart disease. (The first symptoms of tabes appeared in the wife about this time). 6. A girl, died, aged four and a half years, from inflammation of the brain. 7. A girl, died, aged 15 months. 8. A miscarriage. 9. A miscarriage (probably a macerated fœtus). 10. Born dead at term. 11. A girl, now aged 26 years, unmarried. She has had rheumatism and heart disease. 12. A girl, died, aged 14 months. The last half of that family was strikingly and curiously worse than the first half.

The usual history of the syphilitic family such as that related by Pourreyon[3] in a tabetic couple may be given for contrast. There were five pregnancies: (1) a miscarriage at four and a half months; (2) a miscarriage at six months; (3) a miscarriage at seven months; (4) born at term, died aged four months (tabetic pains appeared in the wife); and (5) living and well.

As has been mentioned, no satisfactory evidence of past syphilis is forthcoming in my tabetic pair except such as is derived from the family history. Before his marriage the man had been a sailor and perhaps for this reason syphilis is not very improbable. It was known that the husband and wife were a hard-working, steady, and industrious couple. The history of the daughter's family is also important. There have been six pregnancies. 1. A boy, died, aged five years, from inflammation of the brain, probably tuberculous. 2. A girl, aged 14 years, alive and well. 3. A miscarriage. 4. A girl, aged 11 years, alive and well. 5. A girl, aged eight years. This child is said to have had snuffles when six months old but there were no other symptoms. This and the next child have been examined and no evidence of congenital syphilis can be made out in them. 6. A girl, aged four years, alive and well. The daughter's husband is a healthy man who denies having had venereal disease and no signs of past syphilis can be found on him. The daughter herself also presents no history or evidence of acquired syphilis. She also shows no signs of congenital syphilis but the upper teeth have decayed away. I conclude that this tabetic couple almost certainly had syphilis and that there is no evidence to show the existence of acquired syphilis in the tabetic daughter and her husband.

I propose to make a few remarks on conjugal tabes, on tabes in both parents and offspring, on tabes in one parent and offspring, and also upon the relationship between congenital syphilis and tabes. While admitting the very strong evidence of the identity of the morbid entity in tabes and general paralysis, I shall only refer incidentally to the latter affection. Little need be said about conjugal tabes, for much has been written about it during the past few years, and series of cases have been collected and added to by various writers. The percentage of syphilis in them is given by Hudovernig[4] as 96 and by Raecke[5] as 90. It may be of interest to refer to an instance of conjugal tabes in pure negroes which was reported by Francine,[6] because syphilis is common and tabes apparently very rare among negroes. Usually the disease begins in the husband first and the wife develops symptoms in the course of from two to five years, or even ten years, and in one case 20 years afterwards. In my couple the disease began first in the wife and the interval before the appearance of the symptoms in the husband was one and a half years. It is also noteworthy that if general paralysis takes the place of tabes in the affected couple it usually attacks the husband, the wife being tabetic.

Tabes in both husband, wife, and offspring.—This combination seems to be very exceptional. I have only been able to find one or two instances of it. Max Nonne[7] records a remarkable instance in which all three were infected extragenitally. The child was infected with syphilis by a boy bedfellow and he in turn infected his parents. All three became tabetic, the boy developing tabes five years after the time when he was infected. The same author[8] also refers very briefly to an instance in which both the syphilitic father and the mother became tabetic and the boy was feeble-minded and tabetic. It may, of course, with Gompertz[9] be objected in such cases that the affection in the boy was more in the nature of a genuine syphilitic lesion rather than tabes. Dr. Dawson F. D. Turner[10] recorded a group of cases in which both husband and wife had tabes and their child presented several symptoms belonging, not to tabes, but to Friedreich's ataxia. This child also had aortic disease.

There are instances in which general paralysis has taken the place of tabes in one or more of the individuals of the group under consideration. Thus in a remarkable instance related by Souques[11] the husband was syphilitic and a general paralytic and the wife and two daughters tabetic. In Kutner's[12] group the father was syphilitic and a general paralytic, the wife tabetic, and the daughter, 13 years of age, also tabetic for the past three years. Or, again, the cases of Moenkmoeller,[13] in which the father had tabes and the mother and daughter general paralysis.

To illustrate the importance of the relationship of syphilis to tabes (and general paralysis) the groups of cases recorded by Erb,[14] Finkelburg,[15] and Wertheimer[16] may be referred to in which tabes or general paralysis was present in two of the individuals and syphilis of the nervous system in the third. Finally, to complete the series, in the instance related by Arning[17] (quoted by Erb[18]) all three individuals—viz., husband, wife, and offspring—developed signs of cerebral syphilis.

Tabes in one parent and offspring.—These cases are fairly numerous. Remak,[19] Berbez,[20] Erb,[21] Goldflam,[22] Kahlischer,[23] Dydynski,[24] Brasch,[25] Babinski,[26] Max Nonne,[27] and others have recorded instances of it. A daughter seems to be more frequently affected than a son. Congenital syphilis is the all-important factor in these cases as far as the offspring is concerned, but acquired syphilis may be the cause, as in Max Nonne's[28] case, and also in Kron's[29] case where a child infected from a nurse developed tabes at the age of 13 years. The disease usually appears at the age of five years or upwards, the cases falling into the group of infantile or juvenile tabes. The daughter of my tabetic couple developed tabes in her thirty-seventh year—a late date for tabes to develop on a congenital syphilitic basis. It is also true that we found no marks of congenital syphilis upon her and there is only the evidence provided by her family in favour of congenital syphilis.

It is not, however, absolutely necessary for the purpose in question that the patient should bear the usual stigmata of congenital syphilis—indeed, some go so far as to look upon the tabes itself as a stigma of late hereditary syphilis—and on the other hand, I think we have fairly excluded acquired syphilis. It is interesting to note that in the case of a tabetic woman, aged 22 years, bearing the stigmata of congenital syphilis, Barthelemy[30] deliberately assigns the tabes to congenital syphilis although the patient had been abundantly exposed to the infection of acquired syphilis but had not had any of its usual manifestations. Quite apart from the subject of tabetic couples and their offspring, a fair number of cases are on record in which adult tabes has been attributed to congenital syphilis. Usually the disease has commenced before 20 years of age but in some cases considerably later. Thus Max Nonne[31] quotes a case of tabes in a man aged 32 years, who had suffered from severe lightning pains for two years and who had never been infected with syphilis or addicted to drink. The patient had previously been treated for congenital syphilis and Nonne looks upon the latter as the cause of the tabes in this case. Sabrazes[32] has also reported a most interesting case in a man, aged 42 years, in whom the tabes appeared two years previously. In the absence of a history of acquired syphilis and in the presence of marked stigmata of congenital syphilis the author assigns the latter as the cause of the tabes. Pourreyon[33] in his interesting thesis concludes that when tabes or general paralysis is of congenital syphilitic origin it begins at an age between five and 40 years and he adds that these cases are interesting for the study of precocious or late congenital syphilis. Dydynski[34] even goes so far as to say that if observers do not lose sight of congenital syphilis fewer cases of tabes will be recorded where syphilis has been excluded.

The question, it seems to me, may be put in this form in my cases. Did the tabetic couple merely hand down to their daughter a general vulnerability of nervous tissue to certain noxæ (whether in the form of the syphilitic virus or of stress, strain, &c.), or did they transmit to her the actual virus which would bring about with little or no further provocation the eventual degeneration of the afferent sensory neuron?—and I should answer it in the latter sense. Kahlischer[35] has related an instance of tabes in mother and son, the tabes appearing at the age of 26 years in the latter He excludes to his satisfaction both congenital and acquired syphilis and he attributes the tabes almost solely to congenital hereditary influences. This question of neuropathic heredity in tabes (and general paralysis), at one time much emphasised by the French school, is no longer looked upon as of any very great importance. Yet there have been series of cases recorded where the neuropathic heredity has been marked. Thus Berbez[36] as long ago as 1887 mentioned that among 150 cases of tabes there was a neuropathic heredity in 63 and tabes or general paralysis in a parent in 15 of these cases. Dydynski[37] in 1890, in speaking of infantile tabes (and at that time he would only allow seven such cases), found besides congenital syphilis a neuropathic heredity in six. Probably this neuropathic heredity can only mean a greater vulnerability of the nervous system to the causes of tabes such as the syphilitic virus. It is well seen in cases where, for instance, brothers infected with syphilis from different sources (Erb, Max Nonne, and others) have developed tabes. Among my cases I have records of two brothers, one of whom was suffering from tabes when the other developed an acute general paralysis with fits and died within the year. Apart from this vulnerability of the nervous system, it should, no doubt, be remembered that the syphilitic virus may sometimes be of great potency so far as the nervous system is concerned. This is well exemplified when two or more individuals contract syphilis from the same source as in the cases of Erb,[38] Max Nonne,[39] and Marie et Bernard,[40] and all, or nearly all, ultimately develop tabes (or general paralysis), or again in the truly appalling instance related by Brosius[41] where out of seven glass-blowers infected with syphilis from the same source one developed tabes, another tabo-paralysis, and two others general paralysis. As far as the neuropathic heredity is concerned it would appear to be correct to look upon it with Fehre[42] as nothing more than a predisposing cause and probably not as a very important one.

I have to thank Dr. P. G. Steele, the resident medical officer at the Leeds General Infirmary, and Dr. B. Suggit of the Leeds Public Dispensary for assistance in getting together notes and histories of my cases.

Leeds.

A SIMPLE TECHNIQUE FOR THE BACTERIOSCOPIC EXAMINATION OF SEWAGE.

By W. H. C. FORSTER, M.B., C.M. EDIN.,
D.P.H. CANTAB.,
CAPTAIN, I.M.S.

(*From the Laboratory of the Pasteur Institute of India, Kasauli.*)

FROM the point of view of the laboratory worker in the East the methods at present in vogue for the quantitative estimation of the "organisms of indication" in sewage leave much to be desired. These methods all presuppose the ice packing of samples when necessary and the existence of a laboratory well stocked with the particular apparatus required—preliminary conditions which do not often obtain in India. Thus it has come to pass that although biological methods for the treatment of sewage have been making steady headway in India for some years past, official and public records are silent on the bacteriological side of the question. It will, I think, be readily admitted that, in the interests of the public health, every biological method for the disposal of sewage should be made the subject of systematic bacterioscopic examination. It is unlikely, however, that this will ever be the case whilst our present methods of investigation remain unaltered. A brief survey of some of the methods at present employed in the bacterioscopic examination of sewage will serve to make the point clear. The criteria usually adopted in the examination of sewage are four in number: (1) the total number of organisms per cubic centimetre; (2) the number of bacillus coli per cubic centimetre; (3) the number of streptococci per cubic centimetre; and (4) the number of spores of bacillus enteritidis sporogenes per cubic centimetre. For the purpose of demonstrating the cumbersomeness of the methods of estimation usually employed it will be sufficient if we indicate only those available for the quantitative estimation of bacillus coli and the spores of bacillus enteritidis sporogenes.

The methods of estimating bacillus coli.—1. By the microscopic examination of colonies developing from surface cultivations on phenolated gelatine or agar plates. These cultivations are made either directly from the material to be examined or from preliminary phenol broth cultures. This method is extremely laborious and even in the most practised hands leaves much to be desired in the way of accuracy. 2. By the neutral-red broth method. 3. By MacConkey's method. 4. By Pakes's method. 5. By Houston's method.

Method of estimating the spores of bacillus enteritidis sporogenes.—The only practicable method is by the use of milk cultures heated to 80° C. for 15 minutes and incubated anaerobically at 37° C.

Whichever method of enumerating bacillus coli the routine worker may adopt he has to face the difficulties of ice packing and apparatus. For example, let us suppose that a sewage-disposal system consisting of an open septic tank and a couple of continuous filters is the subject of examination. In this case four samples should be taken, viz.: (1) the raw sewage; (2) the septic tank effluent; (3) the effluent of filter No. 1; and (4) the effluent of filter No. 2.

Let us also suppose that the investigator adopts MacConkey's method of estimating bacillus coli. This will necessitate the use of two of the larger-sized Bulloch's apparatus with incubator space to correspond. Further, as these cultures will be incubated at 42° C. the incubators used will not be available for any other purposes. Incubator space will also have to be found for some 16 or more Buchner's tubes for the estimation of the spores of the bacillus enteritidis sporogenes. The use of other methods of estimating the bacillus coli which do not require anaerobic culture at a special temperature would reduce the requirements somewhat. If, however, we add to the apparatus total that required for the estimation of the total number of organisms and of streptococcus it is hardly surprising that with so many requirements the examination of sewage as a regular routine practice by the controlling authority is considered impracticable. Some simple technique is urgently required which will obviate the use of costly and cumbersome apparatus and which can be rapidly carried out, thus bringing the routine examination of sewage within the scope of the ordinary worker. I do not think that any advantage has resulted from the multiplication of the number of "organisms of indication" requiring quantitative estimation. We have now three such organisms and it is not likely that the number will remain constant. Without enlarging on the subject I may say that in my opinion it will be sufficient for routine purposes if we disregard the streptococcus altogether and take as our criteria: (1) the total number of organisms per cubic centimetre; (2) the number of bacillus coli per cubic centimetre; and (3) the number of spores of bacillus enteritidis sporogenes per cubic centimetre.

In a previous communication[1] I described a simple technique for the enumeration of the total number of organisms in any fluid. In the present communication I propose to describe a technique for the quantitative estimation of bacillus coli and the spores of bacillus enteritidis sporogenes in sewage which I believe will meet the requirements of most workers with slender resources at their disposal and which in point of accuracy will bear comparison with the most complicated methods at the disposal of workers in the best equipped of laboratories. The method, besides materially reducing the quantity of apparatus required, entirely disposes of the ice-packing difficulty. As any modification of technique in the direction of simplicity is likely to appeal to a wide circle I have deemed it advisable to bring the technique in question to the notice of the general body of laboratory workers.

Technique for the quantitative estimation of bacillus coli.—As the technique I am about to describe for the enumeration of bacillus coli is identical with that previously described for the enumeration of organisms—the culture medium alone excepted—I shall merely state the steps of the operation, referring the reader to the previous paper for full details. The following is the apparatus required: three sterile diluting pipettes, three sterile watch glasses, eight nutrose-agar slopes (Drigalski-Conradi medium), and a vessel containing sterile water.

In the three watch glasses dilutions of 1 in 100, 1 in 10,000 and 1 in 1,000,000 respectively are made from the sewage to be examined with sterile water by means of the diluting pipettes. The eight agar tubes are then seeded as follows:—

ube							
1	receives	100 c.mm.	undiluted	sewage	=0·1 c.c.	undiluted	sewage.
2	,,	10 c.mm.	,,	,,	=0·01 c.c.	,,	,,
3	,,	100 c.mm.	1 in 100	dilution	=0·001 c.c.	,,	,,
4	,,	10 c.mm.	,,	,,	=0·0001 c.c.	,,	,,
5	,,	100 c.mm.	1 in 10,000	,,	=0·00001 c.c.	,,	,,
6	,,	10 c.mm.	,,	,,	=0·000001 c.c.	,,	,,
7	,,	100 c.mm.	1 in 1,000,000	,,	=0·0000001 c.c.	,,	,,
8	,,	10 c.mm.	,,	,,	=0·00000001 c.c.	,,	,,

The tubes are then incubated at 37° C. for 24 hours or longer and the last tube showing a reddish colony in conjunction with the next tube which shows no reddish colony will indicate the limits between which the number of bacillus coli present in the sample must lie. Subcultures can then be made and the organism identified by the customary tests. It is important that the agar slopes should be quite dry before use. In practice this end can be conveniently attained by leaving the plugs out of the tubes when the agar is being allowed to set. The plugs should not be replaced until the surface of the agar is dry and glossy. This process can be safely carried out without fear of contaminating the medium. Owing to the remarkable properties of the Drigalski-Conradi medium the isolation of the bacillus coli by this method is an extremely simple matter. The appearance of the coli colonies is so characteristic that they can be detected almost at a glance and the further tests applied practically invariably confirm the first opinion formed. As very few sewage organisms can grow on this medium there is no obscuring of the bacillus coli colonies by other growths and the last tube showing the red colony is usually the last tube showing any growth at all. On account of the excessive humidity of the atmosphere in the Himalayan region at this time of the year I have been unable to test the accuracy of this method in estimating the total number of bacillus coli per cubic centimetre in terms of 10, 100, 1000, &c., but at other times of the year and in countries and places where monsoon conditions do not prevail I have little doubt that such a proceeding would be quite feasible. It would only be necessary to leave the plugs out of the tubes until the liquid sown on their surfaces had evaporated (the tubes being placed in the sloping position) and then to incubate in the ordinary way. In this way the last tube showing coliform growth would display discrete colonies from which the actual number of bacillus coli present in the sample could be calculated. I would emphasise this point, however, that if the number of bacillus coli in the sample be less than nine per cubic centimetre then it is impossible to estimate the number in this way. If the number present be between nine and ten per cubic centimetre then we would expect Tube 2 to show one red colony, all other tubes being free from red colonies. The following calculation will make this clear. Total amount of undiluted sewage sown on Tubes 1 and 2 = 0·11 cubic centimetre. Tube 1 shows no coliform colonies. Tube 2 shows one coliform colony. Therefore there are no bacilli coli in 0·10 cubic centimetre of th test fluid but at least one bacillus coli in 0·11 cubic centi metre. This is equivalent to 9·9 bacillus coli per cubi centimetre (1000 ÷ 0·11).

With a view to ascertaining the accuracy of this method have tested it against MacConkey's method and have foun the results to be identical. A single example of the com parison instituted between the two methods will suffice fo illustration. A piece of fresh horse dung was shaken up i a sterile test tube with a little sterile water. The tube wa then lightly centrifugalised and the supernatant flui pipetted off. A quantitative estimation of the bacillu coli content of this fluid was then made simultaneously b MacConkey's method and by the method which I have jus described with the following result:—

Nutrose Agar Aerobically at 37° C. for 24 Hours.		*MacConkey's Medium Anaerobically at 42° C. for 24 Hours.*	
Tube 1 = 0·1 c.c.	(growth)	Tube 1 = 0·1 c.c.	(growth
,, 2 = 0·01 c.c.	,,	,, 2 = 0·01 c.c.	,,
,, 3 = 0·001 c.c.	,,	,, 3 = 0·001 c.c.	,,
,, 4 = 0·0001 c.c.	,,	,, 4 = 0·0001 c.c.	,,
,, 5 = 0·00001 c.c.	,,	,, 5 = 0·00001 c.c.	,,
,, 6 = 0·000001 c.c.	(sterile)	,, 6 = 0·000001 c.c.	(sterile)
,, 7 = 0·0000001 c.c.	,,	,, 7 = 0·0000001 c.c.	,,
,, 8 = 0·00000001 c.c.	,,	,, 8 = 0·00000001 c.c.	,,

The term growth in the case of the nutrose agar series means that the tube showed reddish colonies and in the case of the MacConkey series that the tube showed gas and acid production. By subculture bacillus coli was isolated from Tube 5 of both series. This method then can stand comparison with one of the most accurate methods at present in use.

Technique for the estimation of the spores of bacillus enteritidis sporogenes.—The great objection to the present method of enumerating the spores of bacillus enteritidis sporogenes in sewage is the quantity of apparatus required. Each sample requires four or five Buchner's tubes or their equivalent according to the method of anaerobic culture employed. This method of estimation, too, is obligatory as being the only practicable one available for routine purposes. My modification merely consists in the reduction of the quantity of apparatus required by the simple process of reducing the size of the test-tubes employed—a device which is rendered possible by the use of the special pipette previously described.[2] In this way the requisite proportion between culture medium and test fluid is maintained in tubes of miniature dimensions The following is the apparatus required two sterile diluting pipettes; two sterile watch glasses; six small test tubes, one tube of sterile milk, one Buchner's tube (large size); and a vessel containing sterile water

---

[1] THE LANCET, June 17th, 1905, p. 1641.

[2] Ibid.

These small test tubes are made from glass tubing, being blown and lipped in the ordinary way. The most convenient size of glass tubing is one giving the following measurements external diameter 0 8 centimetre, internal diameter 0 5 centimetre. In blowing these tubes the bottoms should be made slightly bulbous for a reason which will afterwards be stated, but at the same time care must be taken that the bulb is not so large as to prevent the requisite number of tubes being got into the Buchner s tube The average dimensions of the finished article are as follows length 4 5 centimetres, extreme diameter of bulb one centimetre. These tubes are plugged with cotton wool, sterilised in the autoclave, and dried in an oven In practice it will be convenient to have a large stock of them on hand and after sterilisation they are best stored in a basket For convenience in manipulation a rack can easily be made by boring holes in the lid of a cardboard soap box with a cork borer of suitable diameter The interior of the box is then packed with cotton wool until the internal depth is sufficiently small to allow of the tubes projecting far enough out of the holes for convenient handling. The lid is then firmly bound to the box with string

The steps of the procedure are as follow. The sample to be tested is heated to 80° C for 15 minutes, the necessary manipulations for the enumeration of the total number of organisms and of bacillus coli having been previously carried out With the diluting pipette 0 5 cubic centimetre of sterile milk is introduced into each tube with the usual aseptic precautions From the heated sample dilutions of 1 in 100 and 1 in 10,000 are made in the watch glasses with sterile water The tubes are then seeded as follows —

Tube							
1	receives	100 c.mm	undiluted	sewage	=0 1 c c	undiluted	sewage
2	,,	10 c mm	,,	,,	=0·01 c c.	,,	,,
3	,,	100 c.mm	1 in 100	dilution	=0·001 c c	,,	,,
4	,,	10 c.mm	,,	,,	=0·0001 c c	,,	,,
5	,,	100 c.mm	1 in 10,000	,,	=0·00001 c c.	,,	,,
6	,,	10 c.mm	,,	,,	=0·000001 c c	,,	,,

The tubes are numbered from 1 to 6 consecutively with a pencil for writing on glass The first four tubes are then tied into a bundle with an elastic band and a slip of paper inserted, giving a distinctive number to the sample This little bunch of tubes is then slipped into the Buchner s tube (which has previously been prepared with the usual solutions) and allowed to slide down till arrested by the projecting glass stops It is for this reason that the bottoms of the tubes are given a bulbous shape, as otherwise the bunch of tubes is apt to slip past the glass stops and fall into the pyrogallic acid with disastrous results The remaining two tubes are then slipped into the Buchner s tube and allowed to slide down until arrested by the plugs of the bundle first inserted The Buchner s tube is then corked and is ready for incubation The operation of putting the milk tubes into the Buchner's tube only occupies a few seconds If, as is usually the case, more than one sample is being tested at one time the procedure is slightly different If the investigator is using six milk tubes for each sample—that is, 12 tubes in all, then one Buchner's tube is made to accommodate two samples in the following way The tubes of Sample 1 are numbered with a blue pencil and the tubes of Sample 2 with a red pencil Tubes 1 to 4 of each sample are then tied up into two bundles with elastic bands, the descriptive ticket which is inserted being written with a correspondingly coloured pencil Tubes 5 and 6 of the two samples are bound together with an elastic band without any descriptive ticket These three bundles are then slipped into the Buchner s tube one after the other and the tube corked If the investigator only uses four milk tubes per sample then one Buchner s tube will accommodate three samples, descriptive tickets being inserted into each bundle The utility of this modification is evidenced by the fact that 12 milk tubes can be examined at the expense of one Buchner s tube instead of 12 Buchner s tubes As in the case of bacillus coli if the sample contain less than nine spores per cubic centimetre then the total number cannot be enumerated by means of these small tubes, unless an extra tube containing one cubic centimetre of the test fluid is put up for each sample This, however is in reality unnecessary as any sewage effluent giving a negative result with 0·1 cubic centimetre would pass the provisional standard suggested by Dr A C Houston in the Report of the Royal Commission on Sewage Disposal.

Practical application of the technique —A few notes on the practical application of the technique described in this and the previous communication[3] will not be out of place. For example, let us assume that the investigator is dealing with an installation consisting of an open septic tank and a couple of aerobic filters, and that, further, the works are situated sufficiently far from the laboratory as to necessitate ice packing of the samples in ordinary circumstances. Modifications required for special cases will suggest themselves The following is the apparatus required at the sewage works Diluting pipettes and teats; sterile watch glasses, nutrient agar or gelatine slopes, nutrose agar slopes, two racks capable of holding eight tubes each; sterile water, *sterile bottles for collecting samples*, a *spirit* lamp; a bottle of methylated spirit, a centigrade thermometer, a pair of forceps; a pencil for writing on glass; and a bottle of lysol for cleansing the hands.

Packing of apparatus —The diluting pipettes should be packed by themselves in a box that can be conveniently carried in the hand As to the number required, the more one takes the quicker the work will be accomplished As a minimum I would suggest four, which allows of one sample being done at a time without resterilising and gives a margin of one for casualties The sample bottles should also be packed separately the most convenient form being a short, wide bottomed, glass stoppered bottle of about 30 cubic centimetres capacity At least four bottles will be required. The remainder of the apparatus is all packed in one box, but the packing of some articles requires special notice The watch glasses should be sterilised in a copper cylinder such as is used for Petri dishes This cylinder is then used to transport the watch glasses of which a large number should be taken With regard to the tubes of culture media, the most convenient way of transporting them is to pack them in empty tobacco tins the bottoms of which are padded with cotton wool An ordinary quarter-pound tobacco tin will hold nine tubes and so two tins will be necessary for each sample—one tin to hold tubes of ordinary nutrient agar or gelatine and the other to hold tubes of nutrose agar Provision should be made for four samples By means of a little cotton wool the tubes should be packed firmly in the tins to allow of as little play as possible Before packing, the plugs and mouths of the tubes should be thoroughly flamed and the plugs thrust well home with a pair of forceps. If this precaution is not adopted some plugs are sure to become loosened and fall out in transit The tubes should then be labelled and numbered from one to eight The ninth tube being a reserve for emergencies the label on it should be left blank The remaining articles require no special mention At the works the first step will be to choose a spot for carrying out the technique The mouths of all the tubes should then be flamed and the plugs withdrawn to a convenient distance with the forceps The watch glasses are then taken out and one superimposed above the other in pairs, the forceps after preliminary sterilising in the flame being used for this purpose The pipettes are then sterilised in the flame and placed conveniently to hand The watch glasses are then charged with the requisite amount of sterile water for making the dilutions and arranged in rows of three The samples are then collected and the manipulations necessary for the enumeration of the total number of organisms and bacillus coli carried out The two racks will hold the eight tubes of each series (ordinary nutrient medium and nutrose agar) during this part of the procedure The tubes of each series are seeded alternately with the same pipette. When all the samples have been put up for the total number of organisms and for bacillus coli the sample bottles are then placed in a saucepan containing sufficient water to immerse the bottles almost up to their mouths They are then heated to 80° C for 15 minutes On return to the laboratory the technique for the enumeration of the spores of bacillus enteritidis sporogenes, which do not alter in number during transit, is carried out In this way the ice packing difficulty is entirely overcome, whilst the apparatus required is not beyond the resources of a poorly equipped laboratory I have subjected this method to the most rigorous tests of climate and transport for some months and have never had a breakage or a contaminated tube in the series of controls carried for this purpose. I have, further, never met with a contingency that could not be provided for on the spur of the moment, and I have therefore every confidence in recommending this method to those who are interested in sewage examination questions.

---

[3] Ibid

In conclusion, I should like to point out for the benefit of those workers who deal with more complicated problems in the question of sewage disposal, and to whom ice-packing and apparatus present no difficulty, that the use of the small tubes I have described for quantities of 0·1 cubic centimetre and less in the quantitative estimation of bacillus coli, streptococcus, &c., will so reduce the amount of apparatus and incubator space required that the number of samples capable of being dealt with at one time is greatly increased.

My best thanks are due to Captain G. Lamb, I.M.S., Director of the Pasteur Institute of India, and to Captain W. F. Harvey, I.M.S., Deputy Sanitary Commissioner, Punjab, for much valuable advice and assistance in the preparation of this paper.

Kasauli, India.

FIVE CASES OF TUBERCULOSIS TREATED WITH DR. MARMOREK'S SERUM.

BY HAROLD F. BASSANO, M.A., M.B. CANTAB.,
M.R.C.S. ENG., L.R.C.P. LOND.

IN these days of many inventions hesitation must be felt in using a new therapeutic agent until there is evidence that there is a reasonable prospect of ensuing benefit and no risk of results directly or indirectly objectionable. The recent publication in various medical journals of evidence fulfilling these postulates in favour of the use of Dr. Marmorek's antituberculous serum has induced me to add thereto my own experience of this serum in the treatment of five cases of tuberculosis over a period of 16 months, during which time I have injected about 2000 cubic centimetres. This small experience has been so encouraging that I intend to make a more extensive trial and hope that others may be induced to use it too, so that sufficient scientific evidence may be collected to establish its actual value in the treatment of the different forms of tuberculosis.

The chief conclusions I have drawn from my own observations are as follows: 1. That the beneficial effects of the serum are most marked in the "surgical" forms of the disease. 2. That no objectionable features whatsoever follow the injections except those insignificant discomforts dependent on the introduction of the equine serum into the human body which are not due to the specific antitoxin. I refer to local urticarial rash, tenderness at the site of injection, and slight general malaise, all of which pass off in a few hours. Even these have been rare and in three of the patients entirely absent. 3. That pyrexia is diminished though the fall in temperature is sometimes preceded by an initial rise occurring within 12 hours, rarely exceeding 1° F. 4. That pain in the "surgical" forms of the disease is almost invariably alleviated. In the case of tuberculous peritonitis great relief was constantly experienced within 24 hours after the injection. In the case of hip-joint disease, too, this effect was well marked. 5. That the amount of sputum in pulmonary tuberculosis is rapidly diminished but that an initial increase takes place when the injections are commenced. 6. That in consequence of these results due to the arrested progress of the disease, the general health rapidly improves and the patient gains in weight.

As regards the dosage the method which Dr. Marmorek now recommends is the injection of five cubic centimetres every other day for three weeks to be followed by a clear three weeks' interval, after which the injections are repeated as before. I have not hitherto strictly adhered to this method and in one case have injected 60 cubic centimetres in 12 days, allowing a month's interval, with excellent results. The site of injection is preferably the abdominal wall or thighs and should be varied as much as possible. I have introduced the needle as deeply as possible without penetrating the deep fascia. Antiseptic precautions must of course be observed. An all-glass syringe is by far the most convenient and should be boiled every time before use. The usual serum needles are unnecessarily large. I have always cleansed the skin at the chosen site first with ether and afterwards with a few drops of saturated solution of chinosol, well rubbing with a pledget of cotton-wool, and have sealed the puncture with collodion and wool. If the patient complains of the discomfort of the insertion of the needle this may be overcome by the ethyl chloride spray. The temperature has been recorded every four hours and the sputum weighed or measured every day, and as often as convenient the patients have been weighed.

In recording the following cases I have endeavoured to state the facts concisely but faithfully without quoting unnecessarily full clinical observations from my case-book. I may here state that during treatment with the serum no other therapeutic measures have been pursued or drugs administered except those necessary for the regulation of the bowels.

CASE 1.—The patient, a man, aged 28 years, was first seen on Nov. 20th, 1903. There was a history of progressive enlargement of the abdomen accompanied by pain and fluid stools for one month. On examination the abdomen was found to be much distended, the umbilicus was prominent, and the respiratory movement was imperfect; it was everywhere tender, especially across the umbilical area. A moderat amount of free fluid was present in dependent portions; elsewhere it was tympanitic. The cardiac apex was displace upwards and outwards. The liver dulness was increase upwards. The spleen was not felt. At the left pulmonary apex the resonance was impaired down to the third rib i front; over this area the breath sounds were harsh, with prolonged expiratory murmur, numerous crepitations, and exaggerated vocal vibration and vocal resonance. There was no cough or expectoration. The tongue was furred The motions were loose and of yellow ochre colour. The blood and urine on examination were found to be normal The pulse was 84, the respirations were 20, and the temperature varied between 99·2° and 100·4° F. In December the ascites was diminishing. Slight resistance was felt across the umbilical area. The physical signs at the left pulmonary apex were more marked. There were profuse night sweats and a steady loss of flesh. The temperature ranged from 99° to 100·6°, the pulse was 86, and the respirations were 24.

In January, 1904, the ascites was slight. An increased sense of resistance was felt across the umbilical area. The abdominal pain was severe. There was a considerable degree of emaciation. The temperature was the same as previously noted, the pulse was 88, and the respirations were 25. Early in this month considerable pleuritic friction was heard below the angle of the scapula at the right pulmonary base which extended to the anterior axillary line and was accompanied by slight pain on respiration. From Feb. 9th to April 6th 210 cubic centimetres of Dr. Marmorek's serum were injected in 30 injections. The abdominal pain was greatly relieved during each series. The condition at the end of this time was as follows. The abdomen was flat; there was no ascites; definite resistance was felt across the umbilical area, terminating in a hard, tender mass on the right side. Crepitations at the left apex were less numerous. There were no abnormal physical signs at the right base and no night sweats. The motions were semi-solid. The general condition was better and the appetite was good. The highest evening temperature throughout the period of injections was 101° and the lowest was 99°. The highest morning temperature was 99° and the lowest was 96°. From April 18th to 26th ten cubic centimetres of serum were injected. In May there was much diarrhœa accompanied by pain. During June the temperature was falling, varying between 98° and 99°. The pulse was 92. The physical signs at the left apex were less marked. In July there was much pain in the left side of the abdomen, together with visible peristalsis. The temperature varied between 97° and 99° and the pulse was 100. On August 26th and 29th there were rigors and very acute pain in the left side of the abdomen. The abdomen was tympanitic.

Early in September there was very marked and painful peristalsis starting from the left iliac fossa. Alternating diarrhœa and constipation were present. The pain was relieved by the former. The temperature was rising, the pulse was 106, and the general condition was worse. The symptoms pointed to partial intestinal obstruction in the left iliac fossa. On Sept. 22nd the abdomen was opened in the middle line. Everywhere there was much matting together of intestines, the peritoneum was studded with tubercles, and there were adhesions between the parietal and visceral layers. Especially much matting and thickening were found where resistance had been felt and in the left iliac fossa. Here adhesions were gently broken down as far as possible but no definite constricting band was found. The abdomen was flushed out and eight ounces of sterilised water were left in before the wound was closed. Great improvement followed this operation with disappearance of the painful peristalsis. About the middle of October there was a recurrence of abdominal pain, with violent diarrhœa and increasing emaciation. From Oct. 22nd to Nov. 7th 60 cubic centimetres of serum were injected in six injections. There was no more diarrhœa after the first few injections. The pain was almost gone. The general condition was much improved. In December 20 cubic centimetres of serum were administered in two injections. The improvement was maintained.

From January to April 5th, 1905, 90 cubic centimetres of serum were given in 12 injections. The temperature was almost normal and the pulse was 80. The patient was rapidly gaining weight and there was no pain. At the end of June it was noted that the patient had gained three stone since August, 1904. He looked healthy and well, was much sunburnt, and could walk five miles without much fatigue. His temperature and pulse were normal. The bowels were regular. Nothing abnormal was felt in the abdomen. The pathological physical signs at the left apex had disappeared. The patient was desirous of resuming his occupation.

There was undoubtedly tuberculous infiltration at the left apex and probably the pleurisy at the right base, which was of long duration, was also of the same origin. The prognosis previously to treatment with this serum appeared absolutely hopeless to others in consultation as well as to myself. The laparotomy was imperative for the relief of obstruction and would not otherwise have been performed. Though the subsequent benefit was immediate and great it was only temporary and the patient rapidly lost ground again till the serum injections were recommenced. The patient is now apparently entirely free from any form of tuberculous disease. I think an error was made in discontinuing the injections through July and August, 1904. During these months I was abroad and left the treatment to the discretion of my locum-tenent.

CASE 2.—The patient was a man, aged 32 years. At the latter end of 1903 his left testis with the epididymis were removed for tuberculous disease. In May, 1904, he came under my care. On examination the lower part of the remaining epididymis was felt to be enlarged, hard, and nodular, the swelling being of the size of a large filbert. The testis was apparently slightly enlarged and somewhat tender. The patient informed me that the enlargement of the epididymis had taken place rapidly. From May 5th to June 5th 80 cubic centimetres of serum were injected in 16 injections. The testis became smaller and less tender. The affected portion of the epididymis was decidedly smaller. From June 10th to Sept. 30th 190 cubic centimetres of serum were given in 38 injections. At the end of this period the testis was apparently normal. The epididymis was also apparently normal with the exception of a nodule of the size of a pea at the lower end which felt softer and was adherent to the skin From Oct. 3rd to Nov. 7th 80 cubic centimetres of serum were given in 12 injections. On Oct. 15th the nodule was felt to be very soft and the overlying skin was becoming red. An incision was to have been made the next morning but the skin burst that night with a discharge of thin flaky pus. A slight discharge continued until Nov. 8th, when the patient had to return to London.

For the following notes I am indebted to Mr. H. S. Pendlebury. On Dec. 2nd the sinus was scraped. The scrapings were examined and found to be tuberculous. Serum injections were continued twice weekly, beginning 14 days after the operation and later at intervals of a fortnight up to the end of April, 1905. The thickening in the epididymis rapidly decreased. There was discharge from the sinus at intervals until June, when healing appeared to be complete. The patient's general health was excellent.

CASE 3.—The patient was a man, aged 48 years. In March, 1902, the right testis with the epididymis were removed for tuberculous disease. In December, 1902, there was tuberculous disease of the left epididymis which ended in suppuration with the formation of a profusely discharging sinus. In January, 1903, a tuberculous abscess developed over the left sixth costal cartilage. Later there was pain in the right hip and knee, which rapidly became acute, with limitation of movement at the hip-joint. The patient was confined to bed for three months and afterwards received open-air treatment.

In October, 1904, the patient came under my care. The epididymis was found to be much enlarged, hard, and nodular; a sinus at the inferior end discharged much thin flaky pus. A discharging sinus was observed over the sixth left costal cartilage; no connexion with the cartilage itself was felt with the probe. The right leg was kept at rest in a position of partial flexion and external rotation. Movement at the hip-joint was very painful and the range of movement was very limited. There was some wasting of surrounding muscles. The surface was hotter than the corresponding side and there was some tenderness on deep pressure. The pain in the hip-joint was constant and at times very acute; there was much referred pain in the knee-joint. The patient had been accustomed to hypodermic injections of morphine for the pain. He was losing weight, his general health was deteriorating, and local signs and symptoms were increasing in severity. From Oct. 12th to Dec. 12th 170 cubic centimetres of serum were given in 17 injections. The pain was steadily diminishing. The discharge from the sinuses was more watery and less in quantity.

From Jan. 5th to 22nd, 1905, 60 cubic centimetres of serum were administered in six injections. The pain was only very slight, the sinus in the chest had healed, the epididymis was smaller, and the discharge was clear and very slight. From Feb. 14th to March 2nd 60 cubic centimetres of serum were administered in six injections. The pain was entirely gone and the range of movement at the hip-joint was increasing. The general health was rapidly improving. From March 28th to April 12th 60 cubic centimetres of serum were given in six injections. The patient had gained 12 pounds in weight and had had no more pain. The sinus in the scrotum was almost healed. From May 19th to 31st 60 cubic centimetres of serum were injected in six injections. The patient was still gaining weight. The epididymis felt normal except for a very small nodule at its lower extremity. There was no discharge and the sinus appeared to be healed. Sexual desire, which had long been absent, was returning. The improvement in the condition of the hip-joint was maintained, there was no pain, and the range of movement was steadily increasing. The patient could walk with the aid of a stick for a short distance. He is still under treatment.

CASE 4.—The patient was a man, aged 50 years. In January, 1900, he had pleurisy with effusion at the right side, when paracentesis was performed. In 1901, three shot-like pellets were felt below the skin surrounding the site of introduction of the aspirating needle. In 1902, fusion of these pellets occurred and steady growth of resulting tumour which was diagnosed to be a lipoma. In July, 1903, the tumour extended from the spine of the scapula to just above the crest of the ilium. The diagnosis was unaltered. In September, 1903, the skin became reddened over the lower part of the tumour. The patient consulted a surgeon who advised immediate operation. On exploration the tumour was found to be a chronic thick-walled abscess, situated superficially, and on examination to be of tuberculous origin. The whole abscess sac was freely excised and healing took place by first intention with the exception of the lower end of the wound where a sinus formed, two inches in length.

In November the patient came under my care. Under gas the sinus was freely laid open and allowed to heal by granulation; this healing took place very slowly and irregularly and it was not until February, 1904, that it was complete. Towards the end several exposures to the x rays were made, which seemed to accelerate the progress. The patient went to the Riviera.

In May, 1904, a fresh focus of suppuration started at the upper end of the scar and on exploration the skin was found to be undermined for three inches in a direction at right angles to the original scar. This abscess sac was completely excised. Healing, however, was only partial and fresh sinuses formed in the line of incision and downwards beneath the old scar. The x rays were tried but did not seem to have any beneficial effect. In October the patient again came under my care. Under a local anæsthetic the sinus was slit up and packed with gauze. From Oct. 27th to Dec. 17th 140 cubic centimetres of serum were injected in 14 injections. During this time the wound after quickly assuming a healthy appearance healed rapidly by granulation, healing being complete by Dec. 4th. The patient gained six pounds in weight and professed himself feeling in better health than he had been for years. No inconvenience whatsoever was experienced from the injections, which were made in the neighbourhood of the sinus, and at no time was the patient confined to bed longer than was necessary for the daily dressing. In July, 1905, the scars looked very healthy and there was no appearance of recurrence.

CASE 5.—The patient was a woman, aged 28 years. This case is still under treatment. There is tuberculous infiltration of both pulmonary apices with some consolidation at the right apex. The serum treatment was started in February of this year when the patient, after undergoing sanatorium treatment for months, was steadily losing ground. Bacilli have been found in the sputum on every occasion. From February to the end of June 170 cubic centimetres of serum were given in 34 injections. The patient rapidly gained weight at first and the cough and expectoration diminished but since then her condition has remained unaltered. No definite opinion can be deduced at this stage. A six weeks' interval has been allowed to elapse before recommencing the injections.

In conclusion, I wish to thank Dr. Marmorek for his unfailing courtesy and kindness in supplying the serum and for the valuable advice he has given me from time to time.

Ventnor.

A CASE OF PNEUMONIC PLAGUE.

BY H. B. OSBURN, M.R.C.S. ENG., L.R.C.P. LOND., D.P.H. CANTAB.

BY the Venice Convention very strict precautions are taken with regard to the crews of vessels leaving plague-infected ports. Besides being under observation for some days previously, on the day before departure every man is closely examined by one of the health officers. After this their effects are all disinfected and they are not allowed to land. Again, on the day of departure there is another very close inspection. At these inspections any man with the slightest unexplained rise of temperature or with any recent glandular enlargement, however slight, is rejected. Lastly, for the nine days after leaving port there is a daily inspection of all the native crew by the surgeon of the ship.

On the sixth day after leaving port, at morning inspection, one of the Lascars seemed feverish. The temperature was found to be 100·5° F. The patient, a young, healthy native, looked well and was doing his work; the tongue was clean and there were no enlarged glands or symptoms of any kind. Slight rises of temperature are very common among natives, and in accordance with the usual routine in such cases he was given an aperient and told to report himself next morning. At 7 A.M. next day he came to the surgery looking very ill, with a frequent short cough and with a temperature of 106°; the tongue was fairly clean and there were no glandular enlargements, no pain, and no other symptoms. He was at once isolated in a tent on the boat deck with a native attendant. Two hours later, the patient being in a semi-comatose condition and having a temperature of 106·8°, he was packed in ice, the temperature then falling to 104·5°. The pulse was 120 and the respirations were 28. Examination of the chest gave slight dulness over the right base behind and (?) increased vocal resonance; sibilant rhonchi and a few râles were heard here and there over both lungs but no tubular breathing. But accurate auscultation is impossible on a ship at sea owing to the noises of the engines and the wind. The cough was frequent, with a white viscid expectoration. There was slight improvement during the day and a further examination of the chest revealed only the same physical signs as those noted in the morning. There was now a constant expectoration of white viscid mucus which, of course, was received into a solution of perchloride of mercury. The patient's mind was quite clear.

On the following day the symptoms were entirely those of severe pneumonia, excepting that the physical signs continued to be of the irregular character noticed at the first examination. The temperature, which dropped to 102·5° in the morning, rose to 105·2° at 4 P.M. The patient's mind kept clear; there was still the same expectoration. Towards evening marked injection of the conjunctivæ was noticed.

The next day, being the fourth from the commencement of the disease but only the third from the onset of severe symptoms, the patient and his attendant were removed to an infectious hospital by the order of the local sanitary authority, where he died. The diagnosis of pneumonic plague was eventually confirmed bacteriologically.

No other cases occurred on the voyage, which lasted 13 days after the patient's removal from the ship. No dead rats were found either before or after the case.

There are here unusually exact data for calculating the period of incubation, which must have extended from at least a day before departure to the morning when the first symptoms were noted—that is, seven clear days. But for the daily inspection the case would not have been detected until the next day, as the man was at work and apparently well when first observed, only the fact that he felt hot to the touch causing him to be further examined; the onset of the severe symptoms was at least eight days after possible exposure. The question of rats of course may be raised but no dead rats were found either before or after, which is quite evidence enough that plague did not exist among them. When it does, the way a ship becomes littered with dead rats is quite unmistakeable.

With regard to the diagnosis, the only doubts were as to whether at first it was a possible case of sunstroke; and later, when the chest symptoms became clear, as to how it could be differentiated from an ordinary acute pneumonia. The exceedingly severe onset, the irregular character of the pneumonia of broncho-pneumonic type, the height of the temperature without correspondingly severe pulmonary involvement, and the marked injection of the conjunctivæ all pointed to the invasion of the lungs by something other than the ordinary pneumococcus.

The satisfactory feature of the case was the restriction of the disease to the one man attacked and this in a ship with nearly 600 people on board of whom more than one half were natives. The prompt isolation in a tent on the boat deck, in a free current of air and light, and where absolutely efficient sterilisation could be secured afterwards, is mainly responsible for this. Any attempt to isolate a case of this kind in a cabin would have probably led to dissemination of the disease.

As to treatment, it consisted mainly in the meeting of symptoms as they arose; a distinct amelioration was noticed after the administration of salicylates and the condition of the patient did not seem so hopeless. The necessary removal of the patient to the hospital probably accelerated the fatal ending.

BIDEFORD INFIRMARY.—The sum of £102 has been handed to the authorities of the infirmary at Bideford, Devon, as the result of a house-to-house collection recently made in the town.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF NÉLATON'S OPERATION FOR INTESTINAL OBSTRUCTION.

BY GEORGE P. NEWBOLT, F.R.C.S. ENG.,
SURGEON TO THE ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

ALTHOUGH it is possible in the majority of cases of intestinal obstruction to judge pretty accurately of the nature of that obstruction, yet cases still remain in which after exhausting every available means the diagnosis remains uncertain. If the patient is in good condition and there is not much abdominal distension it is permissible to spend time in exploring, but where the patient is suffering from abdominal distension due to an obstruction of some days' standing anything more than a rapid operation without handling or exposure of the intestines is likely to prove fatal. In this class of case the old operation of drawing up, fixing, and opening the nearest distended coil of intestine as practised by Nélaton still remains to us.

On July 4th, 1904, I was called by Dr. R. D. Evans of Blaenau-Festiniog to see a man, aged 45 years, who was suffering from acute intestinal obstruction. The onset was insidious but was followed by vomiting and total obstruction, no flatus having been passed for 24 hours before I saw him. On examination the abdomen was found to be tightly distended, the pulse was rapid, there was fæcal vomiting, and the tongue was dry. External investigation revealed no cause for the obstruction but as the man had lost flesh I thought that there might be a malignant stricture in the sigmoid flexure.

On opening the abdomen as if for left inguinal colotomy the sigmoid flexure was found to be empty and I therefore fixed the distended small intestine to the abdominal wall, tied in a glass tube, and drained the intestine. A large amount of fæcal matter drained away and as the result the man recovered with an artificial anus in the left iliac region. On Oct. 10th he was sent to Liverpool in order to have the artificial anus closed. The skin around was then eczematous and the discharge at times was watery; portions of undigested food passed at intervals and presumably the opening was high up in the small intestine. The bowels had acted naturally 12 times since the operation. On Oct. 13th an enema of sulphate of magnesium was given through the lower opening of the artificial anus and this was followed by a large stool per rectum. Being convinced that there was a free passage I had the patient anæsthetised and after failing to feel anything abnormal in the abdomen by means of a finger in the artificial anus I clamped the spur. Though this was done on several occasions and an india-rubber tube was placed in the lumen of the gut yet there was no tendency for the motion to pass the right way. The bowels acted normally after an enema but the greater part of the motion passed by the artificial anus.

On May 9th, 1905, I opened the abdomen to the right of the enterotomy wound, having first packed off the latter with gauze. The intestine running up to the artificial anus forming a tube some two inches long was clamped in two places and divided. The end near the artificial anus was everted through the latter and cut away; the other end was sutured, thus closing the opening into the small bowel. The abdomen was closed but great difficulty was experienced in covering over the wound left in the site of the artificial anus. Here the skin was congested and as tight as a drum and it was only by undercutting and sliding the skin that the gap could be filled. The state of the patient caused some anxiety for the first four days as his temperature rose to 102° F. and his pulse-rate to 144, but this had happened before when the spur was clamped. His bowels were moved by an enema five days after the operation and from this time his recovery was uninterrupted. He was able to return home on July 19th and at present is in good health, his bowels acting regularly without an aperient.

The cause of the obstruction was probably inflammatory as when the abdomen was opened in the final operation I found the small intestines adherent to one another in several places but there was no trace of any other change. The clamping of the spur in this case utterly failed to close the artificial anus. Although on the present occasion the operation was a success this is not always, or even often, so. Two cases, both of which terminated fatally, are reported in Vol. XXI. of the Transactions of the Clinical Society, but here there was a volvulus of the cæcum in each instance. I remember a case operated on successfully by the late Mr. Morrant Baker at St. Bartholomew's Hospital in the early "eighties." Sir Frederick Treves says: "It is an operation done in the dark and it leaves the cause of the disorder untouched." But surroundings have to be taken into consideration, and given a case in a small house in the country if the patient can be tided over an acute attack by a palliative measure it is possible that a more scientific operation may be performed successfully at a later stage under more favourable conditions. As a remedy in a desperate case I think it will still remain as a possible way out of difficulties.

Liverpool.

A CASE OF MERCURIAL POISONING.

BY ALFRED WIGHTWICK, M.B., CH.B. VICT.

THE following case is, I think, of some interest. The patient, who had apparently been invaded by pediculi pubis, the infection extending to the axillæ, had freely applied ointment of mercury, using the contents of four boxes, each holding about three drachms two scruples, in the course of three or four days. The night-gown had become discoloured with it and it seemed likely that during the night the face had been rubbed with the hands on which there was probably some ointment. The patient then complained of "nettle rash," which became worse towards evening. The irritation was intense, coming on in paroxysmal attacks, especially at night, the affected parts showing marked signs of scratching. The skin over the lower part of the abdomen was of a bright red colour extending down over Scarpa's triangle. The inguinal glands were enlarged and tender. The axillæ were red, swollen, and tender, palpation causing much pain. The glands felt enlarged. The flexor surfaces of both elbow joints were red, swollen, and painful, the patient saying they were so stiff and swollen that it was impossible to bend them to the full extent. The skin was coarse and desquamating. At times patches of redness, described as "flushings" or "blotches," appeared over the upper part of the chest. There was some swelling under the eyes and the face was described as "all swollen up and blotchy, the upper eyelids so swollen and stiff that the eyes could hardly be opened, the eyelashes standing straight out and the lower lids baggy." Anyone looked at across the room appeared in a mist, the eyes feeling very sore. The edges of the ears were inflamed and tender and later desquamated. The salivary glands were swollen, extremely tender, with increased secretion. The slightest pressure on the teeth caused pain and they generally ached. The gums were swollen and tender, especially so on the inner surfaces. This extended to the palate. The tongue felt "too large for the mouth" and was painful across the dorsum. There was an objectionable taste and odour of the breath was noticed. Though much nausea was present actual vomiting occurred but once or twice, the sensation being that of a bad bilious attack with inability to be sick. The bowels were normal. Headache was severe, feeling as if the two halves of the head, right and left, were being knocked together. The muscles generally, but especially those of the back and thighs, felt as if they were being pinched up, and trembling was noticed in the hands. This continued for a day or two. When getting out of bed one evening the legs felt very weak, the room appeared to go round, and the patient nearly fainted. A week after the appearance of symptoms the patient felt dull with great inclination to sleep, there were "pins and needles" in the extremities, and the bowels were somewhat constipated. This was followed by diarrhœa and the local patches of cutaneous irritation considerably subsided, though in the lower extremities the irritation had extended to the popliteal spaces. This improved in a day or two, the inflammation of the salivary glands with the general tenderness of the mouth being the last symptoms to disappear. I saw the patient some little time after and learnt that there had been a slight return of the cutaneous irritation but that it had only lasted a short time.

Reviews and Notices of Books.

Human Physiology: prepared with Special Reference to Students of Medicine. By Joseph Howard Raymond, A.M., M.D., Professor of Physiology and Hygiene in the Long Island College Hospital, New York City. Third edition. London, Philadelphia, and New York: W. B. Saunders and Co. 1905. 8vo. Pp. 687. Price 15*s*.

Without undergoing perceptible enlargement, which is no faint praise in these days of large students' manuals, this the third edition of Professor Raymond's sensibly written treatise has been very thoroughly revised and most of the recent advances in the subject of which it treats have been incorporated in the text. Amongst the more important of these are the researches of Professor Chittenden on Physiological Economy in Nutrition; of Captain Munson on Army Rations; and Mary Abel on Legumes and Sugar as Articles of Diet, all of which represent work done in America and published in American bulletins, reports, and journals, and therefore not likely to have met the eye of the English reader. The author has evidently paid much attention to the subject of food, and the section devoted to it is really very good, being both clear and accurate as well as concise. There is also an account of recent work upon alcoholic beverages in common use. It appears that from various analyses made by the Board of Health of the State of New York the composition of different samples of whisky and brandy varies within rather wide limits, quite independently, we presume, of retail adulteration. Thus the alcoholic strength of brandy varies from 30·80 to 50·40 per cent. by volume and from 25·39 to 42·96 per cent. by weight. Whisky contains from 44 to 50 per cent. by weight, or from 50 to 58 per cent. by volume of alcohol. Sherry again contains from 16 to 25 per cent. of alcohol. It seems reasonable to draw the conclusion that the different effects produced in those who consume similar quantities of spirit may be in part attributed to the unequal strength of the particular liquor which they habitually drink. Physiologists are by no means agreed as to the action of alcohol in digestion, some believing that it retards, others that it promotes that process. Professor Raymond, in commenting on alcohol as food, remarks that by virtue of the carbohydrates and salts which wines and beers contain they certainly have a food value entirely irrespective of the alcohol which is also one of their constituents. The compound ethers are regarded as assisting digestion by promoting the secretion of the digestive fluids, while the bitter principles are well-recognised stomachic tonics. Used in moderation they are therefore not injurious but used to excess there is danger of their producing superfluous fat, imperfect oxidation, and a resulting plethoric and perhaps gouty diathesis. To the further question, whether alcohol is itself a food, Professor Raymond gives a definite reply, grounding his opinion upon the elaborate experiments of Professor Atwater, that it is undoubtedly a food, but that it is not a necessary food, and that young people at least will act most wisely in abstaining from alcoholic beverages. But he considers it an error to believe that alcohol taken in moderate quantities and in dilute solution acts as a poison, as advanced by total abstainers.

Professor Raymond has introduced new sections into his book describing the movements of the human stomach and intestines as given by Dr. Cannon, as well as others upon hæmolysis and bacteriolysis and on the effect of cold on bacteria. In the sections on hæmolysis and bacteriolysis the globulicial property of the serum is explained as being due to alexins proceeding from leucocytes, whilst the property of agglutinating the bacilli of typhoid fever and the red blood corpuscles is stated to be due to certain agents in the serum named agglutinins and hæmagglutinins. Neither these nor the agents named—cytotoxins, leukotoxins, spermatoxins, and precipitins—have been isolated. Precipitins, obtained by injecting the dissolved albuminous bodies of one species of animal into another, have been employed for the identification of blood-stains, though much technical knowledge is required to procure satisfactory results.

The conditions present in ovarian and abdominal pregnancy are described by Professor Raymond who seems to be in accord with Webster that cases of ectopic pregnancy are rare, and that no gestation can begin its development except in some part of the genital tract derived from the Müllerian ducts such as the uterus and Fallopian tubes. This view as the author observes, rules out both abdominal and ovarian pregnancy. The treatise as a whole represents very well the present state of physiological knowledge as required by medical students and practitioners.

The Practical Study of Malaria and other Blood Parasites. By J. W. W. Stephens, M.D. Cantab., D.P.H., Walter Myers Lecturer in Tropical Medicine, University of Liverpool; and S. R. Christophers, M.B. Vict., Lieutenant I.M.S. Second edition; illustrated. London: Williams and Norgate. Published for the University Press of Liverpool. 1904. Pp. xliv. + 396.

Within 12 months of the first issue of this work a second edition has been demanded. This is partly due to the rapid sale of the first edition and partly to the fact that the advances in tropical medicine during 1903-04 were so rapid and so important that in any work pretending to keep pace with recent knowledge a new edition was imperative. The arrangement of the text follows the plan adopted in the first edition and the excellence of the paper, printing, and illustrations, to all of which we have already borne testimony, is maintained.

Chapter I. is devoted to the preparation of blood films; in Chapter II., normal blood is analysed and the various forms of leucocytes are described. Chapters III. to VI. deal with the malaria parasite in its various aspects and the changes which its presence sets up in the blood, the organs, and the tissues of the body. The important subject of mosquitoes, their anatomy, their life-history, and classification occupies a large part of the volume, no less than 16 chapters (VII. to XXII. inclusive) being devoted to it. Chapters upon blackwater fever, the hæmamœbidæ, the hæmogregarines, the trypanosomata, the Leishman bodies, the spirochætes and spirillar fever serve to indicate the rapid advance in our knowledge of tropical ailments, for when the first edition of this work was issued in 1903 the parasites associated with these diseases, and even the diseases themselves, were unknown. The list of anophelines grows in length at a bewildering rate and the species of mosquito continue to increase as the field of observation extends. Four new coloured plates representing the piroplasma bovis, the trypanosomes of man, birds, frogs, and rats, and the Leishman-Donovan bodies contribute to the completeness and excellence of as well-written and clear an exposition of the subjects dealt with as we could wish to read.

Text-book of Legal Medicine. By Frank Winthrop Draper, A.M., M.D. Harv., Professor of Legal Medicine in Harvard University; Medical Examiner for the County of Suffolk, Massachusetts; Medico-Legal Pathologist at the Boston City Hospital. Fully illustrated. London, Philadelphia, and New York: W. B. Saunders and Co. 1905. Pp. 573.

This volume is intended primarily as a help to students in acquiring the elements of legal medicine but it is also adapted to the needs of practitioners who wish to have at their service the latest advances in medical jurisprudence. Dr. Draper, as a "medical examiner" for the city of Boston for 28 years, has had a large experience in the investigation of the death of individuals in suspicious circumstances. This adds a personal element to his writings which renders the text-book all the more interesting. In addition he cites numerous illustrative cases selected from the standard treatises of forensic medicine. We consider that the description of cases that have actually been brought before the various courts of law is a valuable addition to a work of this nature. It renders a study of the subject more attractive and it also helps in impressing upon the memory of the student the numerous complicated facts which it is necessary to recollect when conducting a medico-legal examination.

The subjects of toxicology and of the medico-legal relations of psychiatry have been omitted from this work. Dr. Draper considers that they have acquired such an importance that they require independent treatment by observers who have made them a special study. He makes some interesting remarks, however, in Chapter XXX., on "Murder by Poisoning," wherein he sets forth in a concise manner the duties of a practitioner when brought into contact with a case of suspected poisoning. Such a position is replete with difficulties; the proper course to pursue is one that may well give rise to great anxiety, and it is useful for the practitioner to have a line of conduct arranged for him.

The whole work is well written and contains a vast amount of information. This will be found easier for American than for English students to apply, since in citations of the law Dr. Draper has confined himself to Massachusetts statutes. His reasons for thus acting may be described as patriotic, for he states in the preface that he believes that "these citations represent the most progressive and most intelligent expression of modern jurisprudence." Perhaps; anyhow the English student of the book will find in it much that is valuable as well as interesting.

From Tokio through Manchuria with the Japanese. By LOUIS LIVINGSTON SEAMAN, M.D., LL.B. London: Sidney Appleton. 1905. Pp. 268. Price 6*s.*

Dr. Seaman's book is full of interest for medical readers, especially those belonging to the naval and military services. He was well qualified for the work of authorship by the varied experience of military surgery and foreign travel which he had acquired as a surgeon with the United States Volunteers in the Spanish-American war which commenced in April, 1898, in the subsequent war in the Philippine Islands, and with the allied armies in the Boxer campaign in China during 1899 and 1900. Dr. Seaman's object in proceeding to the East was to see medical and surgical work in Japan and in the military base and field hospitals as near the front as practicable, but when he arrived in Tokio on June 20th, 1904, accompanied by his friend, Dr. Alexander Trautman of New York, he found that it was impossible to approach the seat of war. Permission was only given to inspect the reserve hospitals in Japan and the hospital for Russian prisoners at Matsuyama. He first visited the military hospital at Hiroshima, then the prisoners' hospital at Matsuyama, then the shipbuilding yards, gun foundries, and machine shops forming the naval base at Kure, and finally the other naval base at Sasebo, where the chief naval hospital is situated. Of the hospital at Hiroshima he says: "Up to the time of our first visit in July there had been more than 600 operative cases and only six deaths. In one of the wards we found 15 surgical cases, six of which had experienced hæmorrhages from the lungs and several in the abdominal cavity as the result of bullet perforations. All were recovering and 10 were able to stand and remain in that position while we were in the ward. Nine patients had been shot through the brain, the orifice of entrance and exit being plainly visible. All were recovering. Another case was that of a man shot directly over the region of the heart. There was no point of exit for the bullet and he probably carries it around with him to-day. Another man was injured by a ball which entered beneath the middle of the right clavicle and went through the lungs."

Dr. Seaman's experiences and impressions seem to have been singularly like those of the author of five articles which have already appeared in our columns under the heading of "Medical Notes from the Far East."[1] In fact, these gentlemen may have met one another, for they were both in Niuchwang at the time of its hasty evacuation by the Russians in the end of July, Dr. Seaman having left Japan for a visit to Manchuria, *viâ* Chifu, and the other being on his way to Japan, *viâ* Shanghai. From Niuchwang Dr. Seaman proceeded to Hsin-Min-Tung, a Chinese town, about 20 miles from Mukden. Here his introductions procured for him the friendship, or at least the hospitality, of the chief of the organised bandits, designated in English spellings as the Hung-hutzes or Chun-chuzes, with several variant forms. After a series of adventures among these people he returned south in order to make his homeward journey to America, *viâ* Shanghai, as he had to read a paper at the International Congress of Military Surgeons to be held at St. Louis. Chapters XIII. and XIV. of the book are devoted respectively to descriptions of the Japanese Red Cross Society and of the methods adopted for the prevention of disease in the Japanese army. Dr. Seaman's narrative is written in a graphic style and contains a number of views, portraits, and other illustrations.

Diet in Health and Disease. By JULIUS FRIEDENWALD, M.D., Clinical Professor of Diseases of the Stomach in the College of Physicians and Surgeons, Baltimore, and JOHN RUHRÄH, M.D., Clinical Professor of Diseases of Children in the College of Physicians and Surgeons, Baltimore. London, Philadelphia, and New York: W. B. Saunders and Co. 1905. Pp. 689. Price 18*s.* net,

THE scientific study of dietetics and the adjustment of diet to the metabolic needs of the organism as a result constitute a great advance on the older empiric methods of constructing diet scales. The preparation of balance-sheets of intake and output both of carbon and nitrogen, and the study of heat values, have combined to place dietetics on a clear scientific basis. In the volume before us a great deal of useful information has been gathered together by the authors, the work being chiefly a compilation of the views of a great number of authorities, frequently given in their own words.

For the arrangement adopted in this work we have nothing but praise. After a general discussion of the problems involved in the chemistry and physiology of digestion the various classes of foods are considered in detail, with special reference to their origin, preparation, composition, and heat values. Beverages and stimulants are next considered and similar information is given with regard to them. Various factors are then discussed in relation to diet, such as concentration, preservation, adulteration, and the occurrence of food poisoning. The feeding of infants, diet in special physiological conditions, and special methods of feeding—such as by enemata and feeding by the nasal tube and stomach tube—are then described in some detail. More than half the book is taken up by an account of diet in disease, each disease being considered separately, and diets appropriate to the condition being suggested. At the end army and navy rations and prison, hospital, and other institution dietaries are given, with various recipes for preparation of food substances for use in the sick-room, together with tables of foods permitted and lists of food prohibited in certain diseases. Except in the sections devoted to diet in disease of the stomach and intestines and to the feeding of infants, where the authors give their own experiences, the diets given are mostly quoted from other authors, and liberal extracts have been made, especially from the works of Atwater, R. Hutchison, Wegele and von Noorden. A considerable degree of repetition occurs, but this is almost unavoidable and is, perhaps, not a disadvantage in a work of this kind which is intended primarily as a work of reference. The authors state in their preface that they have "tried to tell the doctor how to feed his patient," and it will be convenient for the medical man to find what he wants to know quickly. The accounts given of procedures such as rectal feeding and feeding with the stomach tube are detailed and eminently practical. The sections devoted to the feeding of infants and to diet in diseases of children are very comprehensive and contain details of the complicated methods of modification of milk used in the United States. Of these no less than eight separate ones are given, nearly all of them requiring some considerable amount of calculation, so that the information may not be of great use to the busy practitioner, which is stated in the preface to be one of the aims of the work. So-called "laboratory feeding" is, without doubt, a very valuable method of adjusting the diet to the needs of an infant when breast feeding is impracticable, especially in towns, but it is certainly not available in ordinary practice among the poorer sections of the community or in hospital practice, and the simpler and yet effective methods adopted under such conditions might with advantage have been included in the book.

---

[1] THE LANCET, Sept. 24th (p. 920), Oct. 1st (p. 982), and Oct. 8th (p. 1047), 1904; and Jan. 28th (p. 256) and Feb. 11th (p. 391), 1905.

Though there is much to commend in this work yet it is open to criticism in some respects. The account given of the chemistry and physiology of the digestive processes is meagre and by no means up to date. There is practically no reference to the valuable researches of Pawlow and none to important recent work on secretin and enterokinase. The classification of nitrogenous substances is far from satisfactory; fats are referred to as hydrocarbons and in the chemistry of milk the coagulation of caseinogen by ferments is confused with its precipitation by acids. There are not a few misprints and inaccuracies and it is a disadvantage that where several diets are suggested for a given condition little reference is made to their relative values in the authors' opinion.

The Edinburgh Stereoscopic Atlas of Anatomy. Edited by DAVID WATERSTON, M.A., M.D. Edin., F.R.C.S. Edin., F.R.S.E., Lecturer and Senior Demonstrator in the Department of Anatomy, Edinburgh University. Section II.: Abdomen. 50 stereographs. Edinburgh and London: T. C. and E. C. Jack. Price of section £1 5*s*. net. (Price of entire series of 250 stereographs £6 5*s*. net.)

WE find that the second section of this stereoscopic atlas is of equal excellence with the first. There are 50 plates in this instalment of the work and they are divided into the following sections: (1) Abdominal wall; (2) Inguinal region; (3) Abdominal cavity; (4) Viscera; (5) Abdominal aorta; (6) Pelvis; and (7) Bladder.

The plates illustrating the abdominal wall convey a good idea of the arrangement of the muscular and fascial planes, the position of the lineæ semilunares, and the extent of the rectus muscle, though the use of two sets of numerals in the first illustration is confusing. The series which illustrates the inguinal region comprises plates which should be of great value in explaining the anatomy of inguinal hernia. We found it difficult to recognise the pillars of the external abdominal ring in the superficial dissection as illustrated, and the relations of the external saphenous vein to the fascia of the thigh are not so clearly brought out as they might be, but on the whole the plates are excellent. The seven illustrations of the abdominal cavity are especially useful from a medical or surgical point of view. The various hollows or recesses and the positions occupied by the different parts of the intestine are shown. The peritoneal reflections stand out well and one of the plates shows the deformities and malpositions due to tight lacing in a striking manner. The anatomy of the viscera is very satisfactorily demonstrated by means of 21 illustrations, many of which contain more than one view. In addition to the viscera there are views of the stomach bed and of the liver bed when the contained viscus has been removed. Eight plates are devoted to the pelvic cavity, and these illustrations are also very good, although the perspective tends to be exaggerated. In fact, in the whole of this series the various hollows and recesses appear deeper than is natural, whilst the projection of the spinal column into the abdominal cavity is too great.

We are inclined to think that the atlas will not be extensively used by students in their earlier years of medical study. It is necessarily an expensive work, and students of anatomy will always be encouraged by their teachers to learn their work upon the actual body and not to rely on plates, however excellent they may be. In the case, however, of the advanced student and qualified man the matter is different. To students of this class we can conceive that a work like the present may be a great boon and it is to the attention of them that we commend it particularly, in congratulating Dr. Waterston on the progress of his undertaking.

LIBRARY TABLE.

A Primer of Physiology. By E. H. STARLING, F.R.S. London: John Murray. 1904. Pp. 128. Price 1*s*.—This instructive little manual is intended to convey to those who are desirous, as the author remarks, of learning something of the manner in which the normal processes of life are carried on and the broad features of the great functions by which life is maintained. Before, however, even these can be understood the general reader must possess a knowledge of the fundamental facts in physics and chemistry. He must have learnt that each of these sciences has been built up by countless experiments which have collectively shown that nature is invariable, that when the conditions are the same the results are the same, and that if the conclusions drawn by different observers dealing with the same phenomena differ, such difference is due to some condition that has been overlooked in the experiment. The processes that are carried on in the living body are in the highest degree complex and at first sight inscrutable, but careful observation and full reliance on the inviolability of the rules, or, as they are termed, the laws of nature, have enabled physiologists to recognise the physical and chemical processes which accompany many of the manifestations of life. Professor Starling's work may be advantageously read by every medical student before attending a course of lectures on physiology, as it will supply him with a general idea of the subject he is about to study and will enable him to follow intelligently the more extended account of each function that his professor will give in his successive lectures.

The Physiological Aspect of Dietary. By A. S. WAUCHOPE-WATSON. London: Adams Bros. 1905. Pp. 95. Price 2*s*. 6*d*.—The author sets before himself the excellent aim of instructing the public (which, he rightly says, "is led by the great motive power of advertisement rather than by that of actual fact") in the science of proper feeding in sickness and in health. A really satisfactory knowledge of dietetics cannot, of course, be gained without an intimate acquaintance also with the functions of the body and of general chemistry, but definite facts, the outcome of such acquaintance, can be given in elementary treatises to considerable public advantage. The author, on the whole, makes very sound observations in regard to the nutritive value of the various foodstuffs, his remarks on wines and spirits being decidedly to the point. There is an excellent chapter on beef tea. Occasionally the author is apt to overlook the importance of the digestibility of a food as a factor. A section on the feeding of infants contains some discreet remarks, but the composition of a food is one thing and the question of its digestibility another. In discussing gout and uric acid all mention is omitted of the most important factor in food in this connexion—namely, the purins. Again, we think that the remarks about cocoas are too meagre; the supply of cocoa was never more satisfactory than it is at the present time and its adulteration with starch, which he lays some stress upon, is exceptional. It is, further, doubtful whether cocoa is improved, dietetically speaking, by "enriching" it with proteid. On the whole, however, the author's observations are in accord with modern knowledge.

The Courtships of Catherine the Great. By PHILIP W. SERGEANT, B.A., late Scholar of Trinity College, Oxford. With six illustrations. London: T. Werner Laurie. 1905. Pp. 337. Price 10*s.* 6*d.*—Mr. Sergeant may be congratulated upon having produced a work that shows unusual care. His book, however, is disappointing in some respects and particularly in that it fails to enhance the attractiveness of a subject which is of itself intensely interesting. To deal with such a character as that of the great Catherine and only just to interest your reader is to fail in some measure. We do not ask for an enhanced interest at the expense of strict and historic truth, but we regret the occasional dulness of the work. Its great merit, however, is the scholarly accuracy of its pages and for any reader who wishes to know the truth of Catherine's private and political life we can imagine no safer guide. We need not emphasise the interest which that private life has for any student of human nature or of the evolution of European politics in the eighteenth century.

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

JOTHION.

(THE BAYER COMPANY, LIMITED, 19, ST. DUNSTAN'S HILL, LONDON, E.C.)

JOTHION appears as a clear, slightly yellow oil, containing as much as 80 per cent. of iodine. We have not before examined a liquid containing such a high proportion of the element available for administration as such. On treatment with nitric acid an abundance of iodine is liberated. The excipient is readily saponifiable and is in reality an ester. On rubbing a few drops of the oil on the palm of the hand no stain is produced and in a short time the taste of iodine is evident in the mouth. The oil is perfectly miscible with other oils, as, for example, olive oil, and with alcohol, and may be readily incorporated with lanoline for the preparation of an ointment. Jothion is not miscible with water. It is obviously an excellent preparation for the administration of iodine by painting on the skin or by inunction, whether for local application or for general administration as a substitute in the latter case for the mineral iodides. The iodine is very rapidly absorbed.

YEAST PREPARATIONS.

(LA ZYMA, LTD, CLARENS, MONTREUX, SWITZERLAND. AGENTS. T. CHRISTY AND CO, 4, 10, AND 12, OLD SWAN LANE, LONDON, E.C.)

According to our examination these preparations consist of carefully prepared yeast (torulæ cerevisiæ). We found them all to be exceedingly active. The preparations examined included "furonculine dried yeast," "antidiabetic yeast," a dried yeast for veterinary use, and a yeast known as "staupe-antigourmine," which is stated to be a specific cure of dog's distemper. We examined the antidiabetic yeast and found it to be an active preparation and free from sugar. It is obvious from the results obtained that these yeasts are prepared with considerable care and therefore may be trusted for therapeutic purposes.

DRUEDA BREAD.

(F. SUTTON, 11 AND 13, HIGH STREET, SALISBURY.)

The features of this bread, according to the results of our analysis, are a rich proportion of proteid and of mineral salts, including the phosphates. An analysis of the moist bread gave the following results: proteid, 12·78 per cent.; mineral matter, 1·70 per cent; and moisture, 42 00 per cent. The bread yielded nearly 10 per cent. of its substance to cold water and amongst the soluble constituents was proteid. The bread is of excellent texture and of good flavour. It shows a nourishing value decidedly in excess of that of ordinary white bread.

CHAMPAGNE.

(JOSEPH PERRIER, FILS, ET CIE, CHALONS SUR MARNE; LONDON, OLD TRINITY HOUSE, WATER LANE, E.C.)

The samples examined were both derived from the 1900 vintage. Cuvée Royal 1900 gave the following results on analysis: alcohol, by weight 10·69 per cent., by volume 13·24 per cent., equal to proof spirit 23·21 per cent.; extractives, 3·24 per cent.; mineral matter, 0·09 per cent.; volatile acidity reckoned as acetic acid, 0·08 per cent.; fixed acidity reckoned as tartaric acid, 0·64 per cent.; sugar, 1·43 per cent.; and ethers reckoned as ethyl acetate, 0·06 per cent. This is a wine showing decided quality. It is distinctly dry, the sugar not exceeding 1·43 per cent., while it is free from undue acidity. The wine was in sound condition and contained practically no volatile acidity. It has very pleasing qualities. The wine marked First Quality 1900 gave the following results on analysis: alcohol, by weight 12·54 per cent., by volume 15·49 per cent., equal to proof spirit 27·15 per cent.; extractives, 3·20 per cent.; mineral matter, 0·10 per cent.; volatile acidity reckoned as acetic acid, 0·08 per cent.; fixed acidity reckoned as tartaric acid, 0·55 per cent.; sugar, 1·61 per cent.; ethers reckoned as ethyl acetate, 0·036 per cent. This also was a good sound wine but somewhat inferior in quality to the previous sample. It is a little sweeter and contains rather more alcohol. The ethers again are distinctly lower in amount. The quantity of sugar is small, justifying the description of the wine as dry.

PREPARED PEA FLOUR.

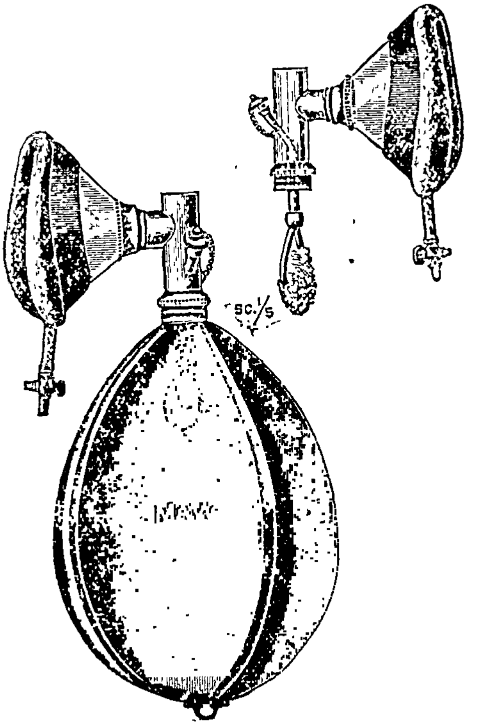
(W. SYMINGTON AND CO, LIMITED, BOWDEN STEAM MILLS, MARKET HARBOROUGH)

As is well known, the nutritive value of the pea or lentil is considerable owing chiefly to the rich proportion of proteid. Unfortunately the proteid contains sulphur which would appear to give rise to the production of sulphuretted hydrogen gas, which has a tendency to produce flatulence. By careful preparation, however, this indigestible quality may be very much modified. Messrs. Symington and Co. have prepared an excellent pea flour in which some of the sulphur, at any rate, is removed, while the constituents are reduced to an easily digestible form. On analysis we found that while the total sulphur was distinctly less in amount than is commonly found in ordinary pea flour the proteids showed an increase. Moreover, the process evidently increases the solubility of the flour, since 16 per cent. of it proved to be soluble in cold water. The method therefore adopted for the preparation of this pea flour may be approved as rendering this nutritious pulse more dietetically suitable.

New Inventions.

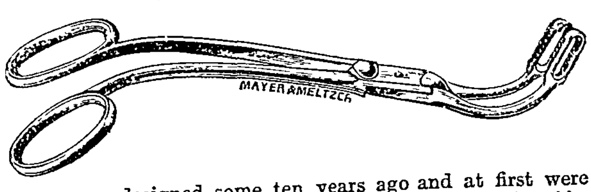
A NEW INHALER.

THE accompanying illustration represents an inhaler which we have received from Messrs. Maw, Son, and Sons of 7, Aldersgate-street, London, E.C. The indiarubber bag has several whalebone supports which prevent its complete collapse. This represents the chief advantage of this inhaler over the many similar patterns designed for the use of ethyl chloride. We do not think that the sponge is anything but a disadvantage, because we believe that the simple method of introducing the ethyl chloride directly into the bag is better than any more complicated process. The whalebone slips undoubtedly are of use and they might well be adapted to the bags commonly used with most forms of ether inhaler.



POST-NASAL FORCEPS.

THE usual Loewenberg forceps and many of the modifications measure from 11 to 12 inches in a straight line from one extremity to the other. The examination of a few skulls and moist sections show that this is unnecessarily long. The instrument here represented only measures six and a quarter inches from tip to handle. With the patient's mouth wide open, as it must be in all cases requiring this instrument, this length is sufficient, even for full-grown adults, while the shortness and lightness of the forceps lend precision to all manipulations in the post-nasal space. The forceps are otherwise but a slight modification of the form known as Jurasz's.



They were designed some ten years ago and at first were employed in all cases of removal of naso-pharyngeal adenoids. Since adopting the curette this use of the forceps has been almost entirely abandoned. But the instrument is still, owing to its small bulk, better adapted than the smaller curette for removing adenoid growths from infants in whom the post-nasal space is both relatively and absolutely so remarkably small. In all adenoid operations it will also prove useful to have these forceps at hand for grasping any detached mass which may fall out of the caged curette or for removing any tags of growth found hanging after the operation. Apart from the adenoid operation, these forceps are frequently of service in removing polypi or cysts from the choanæ and in dealing with foreign bodies, necrosis, and new growths in the post-nasal space. As they serve as carriers of cotton wool or gauze they are convenient for making applications and dressings or for tamponing the cavity. They are made in one size only by several instrument makers.

FOREIGN DEPARTMENT.

*On the Mode in which the Sympathies between the Ear, and other Organs, are effected.**

DIFFERENT sounds produce pleasant or unpleasant sensations, and operate powerfully on the animal and vegetative functions. Very strong sounds, or sounds of a certain kind, produce very singular and striking effects in persons whose nervous system is easily excited. The celebrated Bayle always fell into convulsions on hearing the fall of water from a pipe (*Esprit des Journaux*, Nov. 1793); and Rousseau states, that he knew a woman who could hear no kind of music without being thrown into convulsive laughter. Tissot also relates the case of a person, in whom the sound of music brought on epilepsy. Sounds not only put the brain in activity, in consequence of their action on the auditory nerves, but they exert also an immediate influence on the auxiliary nerves of the ear derived from the fifth pair, by which different organs of the head are brought into sympathy. A violent sound sometimes causes a sudden and involuntary closure of the eyelids. Some persons complain of a peculiar sensation being produced in the teeth by the rubbing and cutting of glass, which is commonly called putting the teeth out of edge. These, and similar appearances, can only be explained by the communication between the chorda tympani, and the branches of the fifth pair. There are also other phenomena, which show that the organs of vegetative life are affected by certain sharp sounds, and which can only be explained by the connexion of the chorda tympani, with the branches of the glosso-pharyngeal nerve distributed to the tympanum, and of the sympathetic. Paullini* relates a case of a man who invariably vomited on hearing music; and Pechlin† makes mention of a person, in whom the mechanical irritation of the external ear caused vomiting. It is also well known, that persons of weak nerves sometimes become faint by the tunes of the harp; and there are several instances on record, of the respiratory and urinary organs being affected by a similar cause.

As the ear is connected with the sympathetic, it not unfrequently happens that in primary affections of the abdomen, this organ also suffers. This can only be explained,‡ by the connexion of the sympathetic nerve with the glosso-pharyngeal. Sand mentions § the case of a person with an ulcer at the bottom of the stomach, who complained of a pain extending from the stomach to the left ear. Difficulty of hearing, and complete deafness, are sometimes produced by affections of the abdomen. To this cause belongs the periodical deafness which comes on with spasms of the abdomen and intermittent fever, and again disappears. Wardrop || mentions the case of a child labouring under intestinal worms, who became amaurotic, and nearly lost the power of hearing; the functions of both senses were restored after the expulsion of the worms. Sometimes, also, difficulty of hearing, and deafness, come on during pregnancy, and disappear after delivery.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 9, 1905.

The Presidential Address at the British Association

The doctrine of natural selection, or survival of the fittest, is in most men's minds associated only with the speculations of Darwin and Wallace as to the origin of the various species of animals seen at the present time and with the evolution of the human race from some more lowly type, but it now seems that the same process is at work throughout the universe in inanimate as well as animate matter and that the theory is comparable in its range with the theories of gravitation and of the conservation of energy. The luminous and fascinating address delivered by Professor G. H. Darwin before the British Association for the Advancement of Science at its recent meeting in South Africa shows how the process of elimination of weaker forms of matter is at work in the physical world, alike in the minutest particles and in the vast systems of suns and planets which have been discovered by the astronomer. The preparation of radium and the study of the remarkable properties which it exhibits, if they have not revolutionised scientific views as to the ultimate constitution of matter, have at least confirmed beyond possibility of doubt speculations to which other discoveries in the realm of physics had gradually led. We now know that the chemical atom, the smallest particle of matter which is capable of entering into combination with a similar particle of another substance, is not in reality an ultimate indivisible body, but that each atom is made up of many smaller corpuscles or electrons of infinite minuteness, held together by some unknown force and yet in all probability repelled one from another by a similar yet opposite force, as particles charged with like electricity are mutually repelled. Professor J. J. Thomson has succeeded in calculating mathematically the behaviour of some 70 such particles charged with negative electricity contained within a sphere positively electrified—truly a triumph of deductive reasoning—and finds that many of the peculiarities of a chemical atom would be thus reproduced. Yet there are reasons for believing that the simplest element—hydrogen—consists of atoms containing about 800 corpuscles, while the heavier atoms contain many times this number. Such composite structures as these last are not indefinitely stable and in the course of time they break down spontaneously into simpler and more resistant elements. We have an actual example of this process in the case of radium which is constantly throwing off particles by disruption of its atoms, a more simple element remaining behind. In any given portion of radium this decomposition only takes place gradually, a certain percentage of the component atoms breaking down in a unit of time. The life of the element is thus not eternal but it may be very long. It is probable that a similar process takes place in all other substances, but so much more slowly that we are unable to recognise the change. If the life of radium be 1000 years that of other elements may be millions but they may yet not last for ever. The process of evolution or struggle for existence between non-living substances is a contest of stability, the unstable constantly breaking down into more stable forms better fitted to survive in the conditions under which they find themselves. Constant change, not permanence of matter, is the lesson of recent discoveries. It is curious to reflect how exactly we are thus brought back to the views propounded by the old Greek philosopher Heraclitus who taught that all nature was in a constant state of change: nothing actually "existed" but everything was in a condition of "becoming." The atomic theory and the persistence of the more stable forms of atomic combinations while others were destroyed were also taught by a Greek thinker, Democritus, and a poetical statement of his doctrines is to be found in the Latin poet Lucretius, whose account may be read with interest at the present day as showing an extraordinary instance of successful guessing at truth when there were not enough facts known to render possible the construction of a really scientific hypothesis.

In the second portion of his address Professor Darwin shows the applicability of the evolutionary theory to the infinitely great as well as to the infinitely little. Change to forms of greater stability has been the keynote of the development of the solar system of which our earth is a part and doubtless of those other systems which astronomy has made known to us. The nebular hypothesis supposes that originally the sun and its attendant planets existed in the form of a mass of gaseous matter revolving upon its own axis. The central portion of this gradually contracted and solidified, giving rise in the process of shrinking to the production of intense heat. Thus the sun was formed in the centre of the system. According to this hypothesis the planets were formed by the coalescence of rings of gaseous material which had been thrown off from the central mass as it shrank and solidified, owing to the centrifugal force generated by increased rapidity of revolution; but this explanation appears untenable, since a ring of material substance would tend to solidify around its centre of gravity in the sun, not round any point in its circumference. Another mode of the formation of satellites is set forth by Professor Darwin, depending upon the behaviour of a rotating sphere of liquid, supposing that its velocity of rotation is constantly increased. The original sphere will first tend to assume an egg-shaped contour; next one end of the egg will enlarge and give rise to a projecting filament with a bulbous extremity; and finally the body will take the shape of two masses held together by a slender thread of matter. This will break and there will remain two separate masses, a smaller and a larger, the less revolving round the greater. This account seems to apply to the origin of the earth and its satellite the moon, for calculation shows that at one time the moon revolved at such a rate as to face always the same point of the earth's circumference, a fair proof that it was formed by breaking off from the larger body.

If we ask whether we have even now attained to a stable condition of things in our portion of the universe we are again obliged to return a negative answer. From the point of view of animal life perhaps the most evident lack of permanence is seen in the gradual wasting of the sun's heat by continual radiation into space, although it is interesting to note that it is now held that the process of condensation already mentioned is not the sole source of this heat, radio-activity being credited with some of it—a change of view which has brought the physicists into agreement with the geologists by enabling the former to concede the possibility of a much greater age of the world than they could have admitted on the older hypothesis. But the relations existing between the earth and its own satellite are themselves undergoing slow change owing to the gradual retardation of the rate of rotation of the former. The earth's surface is largely composed of water and by the attraction of the moon this water is being constantly drawn up into a heap in a direction towards the satellite, this upheaving constituting the tides. As the earth revolves the tidal flow of the water constitutes a slight check upon its motion, friction occurring between the surface of the earth moving in one direction and the water being drawn in another. In itself this is but a comparatively minute force, but acting over a long period of time a small cause produces great results and this infinitesimal brake upon the wheel is gradually bringing the revolution of the earth to a standstill. Thus in great things as in small there is no such thing as permanence. "The old order changeth giving place to new" not only in human affairs but in the heaven above and the earth beneath, and the appearance of changelessness in the universe around us is only due to the minute length of human life compared with nature's cycle, just as a revolving wheel illuminated by an electric spark seems to our eyes to be stationary. To the "spectator of all time and existence" the universe would offer the spectacle of ceaseless mutation and living substance would be distinguished from other matter merely by the relative speed of its transformations.

The Rational Treatment of Mangled Limbs.

In the first half of the nineteenth century the subject of the rational treatment of mangled limbs was much discussed, indeed, it may be said to have been thrashed out by Larrey, Liston, Guthrie, Hammick, Fergusson, Faure, and others, while in 1843 Dr. Henry Reid of Manchester obtained a gold medal at the University of Edinburgh for a thesis on this very subject. Then came Pasteur and Lister, since whose discoveries the surgery of disease has overshadowed the surgery of trauma, the modern surgeon paying less attention to fractures, dislocations, and sprains than did his great predecessors of the last century because his sphere of work has been so indefinitely increased. In another column will be found a letter from Mr. C. Hamilton Whiteford of Plymouth which is an echo of an old controversy on the treatment of mangled limbs. The indications for amputation before the days of antiseptic doctrines were laid down as follows:—The rupture of the main vessels and nerves, the opening of a large joint, the compound comminution of a bone, the separation of very large areas of skin (especially if they took the form of a cuff and were turned down, as when limbs were caught in rollers), and, lastly, excessive fouling of the wound, especially with humid mould and earth. There was even in Liston's time a strong feeling against needless amputation, but the dangers to be combated were different in degree and conservative treatment had not the chances that it possesses in these days when antiseptic technique has been carried so far. Hæmorrhage, collapse, and fever, which we now know to mean septic infection, were recognised as the essential risks against which provision had to be made. All were agreed that the hæmorrhage must be arrested at once by the rapid application of forceps or ligatures or by tight bandaging over a compress. It was generally accepted that to amputate during collapse would almost certainly prove fatal. Sir William Fergusson said in 1857: "It is a maxim almost invariably applicable never to amputate whilst the patient is in a state of shock," but as Mr. Jonathan Hutchinson, sen., urged about the same date the sooner the amputation is done when the shock is combated the better the results. The surgeons of 50 years ago recognised the terrible mortality which followed "intermediary" amputations of mangled limbs—i.e., amputations after the expiration of 24 hours from the receipt of the injury—although they did not explain it. Now we know that immediately after the accident the infection of tissues is strictly local and that an amputation performed then will be through aseptic tissues, but that in 24 hours' time the micro-organisms have spread by multiplication to the deepest recesses of the wound. The lymphatics of the limb above are full of them and an amputation performed then passes through virulently infected tissues and permits the most rapid absorption from the raw muscular surfaces of the flaps. The older surgeons knew that if the patient survived the acute stage of suppuration and amputation were performed some weeks later, when sepsis had become chronic and hectic had commenced, the results were relatively very favourable, although the theories of acquired immunity had not been formulated.

The treatment of mangled limbs has been greatly improved by the application of antiseptic methods and is generally agreed to be as follows, the essential risks being still hæmorrhage, collapse, and septic infection:—The clothing should be rapidly cut away and removed. The hæmorrhage if active must be arrested at once. All but large arteries can readily be controlled by an antiseptic compress when a tight bandage should be locally applied. Tourniquets should be avoided; at any rate they should never be applied for more than an hour, and even in that time they will seriously interfere with the vitality of the future flaps. The shock must then engage the medical man's attention. Morphine may be injected at once and with no stinted hand. A third of a grain combined with a thirtieth of a grain of strychnine for an adult is a usual dose, followed by a sixth of the former and a sixtieth of the latter every hour until sleep is induced. It is not only pain which is thus relieved, but anxiety and vascular failure, for the pulse rapidly improves and becomes even and full and the extremities grow warm whilst the restlessness subsides. The patient is sure to be in urgent need of fluid if he is conscious, when his thirst may be met by moderate quantities of water or weak tea frequently repeated. It is well to avoid the administration of an anæsthetic at this stage because of the risks of subsequent vomiting and further heart failure. If the loss of blood has been very great and the collapse profound, intravenous transfusion of saline solution may be unavoidable. The patient should be wrapped in blankets or rugs and, if they can be obtained, surrounded with hot-water bottles or hot bricks. In an hour or so when narcosis is complete the limb may be uncovered, cleansed, and fixed upon some apparatus for transportation. The medical man on the spot can do more than any other subsequently to benefit the case. On no subsequent occasion can so much be done to prevent extensive septic infection. A free use of hot water, soap, and a razor will remove many of the sources of infection before they have had time to multiply or to be absorbed. Hopelessly soiled and torn tissues may be cut away without pain to the patient and a firm antiseptic compress may be applied over the entire wound. Splints or improvised supports should then be applied, one of the best of these being a voluminous pillow tied around the limb by strips of bandage. Such is the routine treatment of a patient with a badly mangled limb to whom the surgeon has to render first aid. In spite of the obvious simplicity of the teaching we have thought it well to give the details, as it is certain that some practitioners are a little too willing to listen to the suggestions of friends, bystanders, or witnesses of the accident and to have the patient transported at once to a hospital. This course is bad for the medical profession, as it leaves the impression that only at the hospital can serious cases be treated, and it is bad for the patient, as the earlier the measures preventive against sepsis can be taken the better chance he runs.

The patient is now ready to be removed to some convenient spot where the question of amputation can be discussed and, should it prove necessary, the operation performed. He should be conveyed in the recumbent position and with as little jarring as possible while the various provisions against shock must be continued during the journey. Many such cases arrive at hospitals several hours after the accident when it is found that nothing has been done except partially to arrest the hæmorrhage. This is, as a rule, the result of the impatience of the relatives to get the patient to a hospital. The operating surgeon is then on the horns of a dilemma should he have to decide that amputation is necessary. If he gives an anæsthetic, cleanses the wound, and amputates at once the patient will die from shock. If he waits completely to combat the collapse until 12 or 18 hours after the accident sepsis will have spread far and wide through the tissues and the patient will die from acute sapræmia or septicæmia. As a rule, if amputation is unavoidable he strikes a mean and removes the limb after some two or three hours have been devoted to relieving the shock. Should a bad result follow it is rather to be attributed to the failure of the early treatment than to any irrational desire to remove a limb. It will be seen that in many matters we agree with Mr. WHITEFORD'S views as expressed in his letter but we cannot help thinking that his experience has been unfortunate. In all the hospitals with which we are acquainted the surgeons are fully alive to FERGUSSON'S dictum that no amputation should be performed during the stage of shock, and Mr. WHITEFORD does not seem to have appreciated the increasing danger of amputating mangled limbs after the twelfth hour. When such a limb must be removed it should be done at the earliest possible moment after the shock is combated.

Research in Medicine.

DR. A. E. WRIGHT, formerly Professor of Pathology at the Army Medical School at Netley and now pathologist to St. Mary's Hospital, has thrown himself with characteristic energy into the work of endeavouring to persuade the public that the endowment of medical research is the most pressing necessity of the time in which we live. An article entitled "The World's Greatest Problem" appears under his name in the *Liverpool Daily Post* of August 30th, and in this he dwells at some length upon the vast importance to the community of the problems presented by disease, upon the insufficiency of medical knowledge with regard to them, and upon the legitimacy of the demand upon rich people that they should give of their abundance in order that this insufficiency may be remedied. "*Qu'allait-il faire dans cette galère?*" is a question which the spectacle of a professor of pathology contributing to a provincial daily paper causes to spring unbidden to the mind; but we understand that Dr. WRIGHT has consented to formulate his opinions for the use of an organisation of gentlemen interested in public health and that the manner in which the results shall be employed has been left in their hands. If this be so, these results will probably be given to the public through various channels and, it may be, in slightly differing forms, but we may clearly take the article to which we refer as a deliberate pronouncement upon points of great public importance. Dr. WRIGHT is a pessimist of the most pronounced type. He declares the prevailing belief "that the medical art of to-day can effectually intervene in the course of disease" to be an illusion and one which ought to be dispelled. He tells us that the "thoughtful and conscientious physician" when confronted with an acute bacterial invasion does not conceal either from himself or others that he is "quite in the dark" and that he can neither foresee nor determine the issue of the conflict. Fully conscious of the limits of his knowledge, and conscious also of the risks of ignorant intervention, the thoughtful physician aforesaid dismisses from his mind all idea of positive treatment. He contents himself with laying aside the drugs which he feels to be useless and with looking after the feeding of his patient. From this sweeping statement Dr. WRIGHT excepts only "one or two infective diseases which can to some extent be controlled by remedies placed in our hands by chance" (we presume the intermittent fever group) and the case of diphtheria, "a disease for which an effective remedy has been furnished by medical research." As regards others, it may be affirmed with confidence, Dr. WRIGHT believes, that the medical art, as at present practised, can do nothing to avert death from a virulent bacterial invasion or to bring about a cure.

Proceeding from the premisses above laid down, and having previously asserted that "of all the evils which befall man in his civilised state, the evil of disease is incomparably the greatest," Dr. WRIGHT goes on to explain, lucidly and accurately, circumstances which appear to him to stand in the way of active prosecution of inquiries by which the dark places of medicine might be illuminated. He points out that hospital physicians, being unpaid, cannot spare the necessary time for unremunerative laboratory work, and he attributes to economic reasons the "fact"—he states the debateable point as a fact—that we are not making any effort worthy of the name to solve the problems of disease. We have not in England any appreciable number of workers engaged upon the task of medical research. The economic reasons for this are that a young man who proposes to take up medical research as his lifework finds himself immediately confronted in his own person with the fundamental and primitive problems of obtaining subsistence, and clothes, and a shelter over his head. Even if appointed to one of the research scholarships which have been recently founded for the purpose of launching the student upon a career of research, the problem will only be staved off a little. Dr. WRIGHT wishes it to be known universally that "the scientific knowledge which alone can avail in the conflict with disease is—practically all of it—still to seek," and that the first duty of all members of the community is to do something towards rendering the research successful, "towards making provision against the day when they themselves, and those near and dear to them, will be in the grip of disease." Especially does he address himself to those careless rich who nurture the comfortable faith that when they are ill Dr. A, or B, or C, whom they know, or failing him, Dr. X, or Y, or Z, in London, or Paris, or Berlin, will be able to cure their diseases; and he tells them that when their dark hour arrives the wealth in which they trust will be impotent to purchase for them any effectual scientific aid. Now, he assures them, is the accepted time at which it is the duty of every far-seeing man to reflect upon the problem as to how the proper kind of workers can be enlisted for the purpose of medical research, and how the proper training and skilled direction can be provided for the workers. Until, he concludes, the "economic conditions shall have been so altered as to attract to the work of research a proportion of the best ability of every country the task of providing for that scientific skilled direction of medical research will be the really difficult problem."

We have been very desirous to do no injustice to Dr. WRIGHT'S position or arguments and have therefore, to a considerable extent, stated them in his own words, but we do not find his opinion of the position sound or his arguments free from fallacy. It is obvious, too obvious to be worth saying, that much of the recently acquired knowledge as to the production of disease by invading organisms is in its infancy. There open out from what we have learned many fields of inquiry which must be diligently traversed before the full value and the complete application even of what is now known will be in our possession. In the case of a large number of invading organisms, we do not at present know any means of destroying them without injury to the person whom they have invaded; but, admitting this to the fullest extent, we believe that we shall carry with us the assent of every experienced clinical physician when we affirm the power of judicious treatment, even of drug treatment, to control or modify many of the results of what Dr. WRIGHT calls the conflict. A phrase familiar to our forefathers, the phrase "to obviate the tendency to death" is one that has by no means lost its significance, and the means of accomplishing what it suggests are manifold. The employment of these means may often be far more scientific, in the proper sense, than would be the administration of the antidotes which are what Dr. WRIGHT apparently seeks from science. We regret, in common with all reasonable people, that scientific research should be hampered by the fact of its immediate pecuniary unproductiveness, and we should gladly welcome any funds or endowments by which the difficulties hence arising might be even partially overcome. We are, nevertheless, entirely sceptical as to the possibility of developing a capacity for research by any means of such transparent simplicity as the mere provision of stipends for the workers. The work, to be conducted successfully, requires the guidance of mental capacity of a high order, and this is not to be secured either by a laboratory training or by a certain if modest income. When Nature endows the world with a PASTEUR or a FARADAY there soon ceases to be any doubt concerning either the character or the value of her gift. America knows well that when ambitious mediocrity is placed in the chair we get a type of professor in whose person loquacity not always inspired by accuracy is made to represent the latest achievements of scientific labour. Hypothesis is piled upon hypothesis, Ossa upon Pelion, and still we are not perceptibly nearer to the clouds. We shall be content for the medical profession with that moderate rate of secure progress with which the last few years have rendered us familiar, a progress marked, on the one hand, by antiseptic surgery and by its effects, on the other, as Dr. WRIGHT admits, by a remedy for one frequently fatal disease and by much increase of knowledge concerning the causation of others. We should be the last persons to undervalue research, especially when conducted by men gifted with the necessary caution, imagination, and absolute fidelity to truth as distinguished from hopes and from conjectures, but we should expect little from a medicine of antidotes which led to any under-valuation of clinical study or from any attempt to confuse and blend together the altogether dissimilar duties of a student of natural philosophy and of a medical practitioner. The former may sleep upon his doubts and may repeat and vary his experiments; the latter must act for the best in the particular emergency which is before him.

Annotations.

"Ne quid nimis."

THE CARE OF THE SICK AND WOUNDED IN THE BOER WAR.

THE strain placed upon the Royal Army Medical Corps during the South African war revealed the weak points in our army medical organisation and plainly demonstrated the inadequacy of our existing establishment. That the officers of the corps did excellent work was allowed by all, while the breakdowns that occurred were due mainly to under-manning and to difficulties of transport, but at the end of the war it was recognised that reforms of a thorough nature would have to be introduced in order to place the army medical organisation upon a satisfactory footing. Accordingly, a Royal Commission was appointed to consider and to report upon the care and treatment of the sick and wounded during the South African war, and to recommend measures calculated to prevent the recurrence of such loss of life and sickness as marked that campaign whether caused by the lack of medical aid or the absence of sanitary organisation. The report of the Commissioners was published in our columns at the time of issue and the recommendations will be found in THE LANCET, March 9th, 1901, p. 734. An abstract of these recommendations has been issued recently, together with the action taken thereupon. In accordance with the recommendation of the Commission a reorganisation committee, of which the Secretary of State for War was chairman, was appointed and dealt with the organisation of the Army Medical Service generally and delegated to an advisory board the consideration of certain points. Some of the subjects have since been fully considered by this board while some are under the consideration of the Army Council. The result, so far as action has been taken upon the recommendations of the Commission, is as follows. The establishment of medical officers has since the war been increased by 125 and the establishment of quartermasters, warrant officers, non-commissioned officers, and men, including provision for South Africa, by 1216, and the question of further increases in both categories is still under consideration. The equipment provided by the Mowatt reserves for three Army Corps, one Cavalry Division, and Line of Communication Troops has been completed and is being revised. By a Royal Warrant issued on March 26th, 1902, the pay of medical officers has been greatly improved. A college for the instruction of officers has been opened in London and a permanent building is now in course of erection at Millbank. All officers of over five years' service are required to attend a six months' course of instruction, which includes clinical teaching in the various civil hospitals in London by civilian professors. Officers passing certain standards at the examination after the course are eligible for accelerated promotion up to a period of 18 months, and officers who distinguish themselves in selected subjects are eligible for employment as specialists with extra pay. Promotion to the higher ranks is now made upon a system of strict selection based upon positive merit. It is stated that as a result of these regulations the supply of candidates has been of the most satisfactory nature. A Royal Warrant was issued in March, 1902, approving of the establishment of Queen Alexandra's Imperial Military Nursing Service. This warrant is believed to have greatly improved the conditions of service of nurses and is attracting highly qualified nurses. An increase of 259 nurses has been made to the peace establishment and this number is being recruited so that the needs of all important military hospitals will be met. The scale of nurses for fixed hospitals in war has been largely augmented. The appointment of properly qualified Sanitary Officers to all commands at home and abroad has been approved, and already, in all home commands and the important commands abroad, these Officers have been appointed. To insure a satisfactory ambulance wagon being provided a prize was offered and many firms competed. It is stated that after exhaustive trials of many patterns wagons of a thoroughly satisfactory character have now been selected. A special tent (a modification of the Indian pattern E.P. tent) has been designed and made and has undergone successful trials. The provision of further reserves of officers and orderlies is still under consideration. A scheme has been drawn up for the establishment of a reserve of civilian surgeons who will receive military training. A scheme of special enlistment to provide a sufficient reserve of trained orderlies is also under consideration. From all of which it will be gathered that much has been already accomplished in the direction of reorganising our army medical department. As to the working of these reforms some time must yet elapse ere criticism can be passed that will be quite just. As each reform has been announced, we have noticed it and welcomed it; and now that an official summary of the actions taken on the recommendations of the Royal Commission has appeared all will regard what has been done as an earnest of good intentions. It is sincerely to be hoped that our Army Medical Service may take rank in efficiency with the medical departments of any army in the world. The appointment of properly qualified Sanitary Officers to all commands at home and abroad is a departure which is especially to be commended. The need and value of such Officers have been emphasised in the most marked manner in all recent wars.

THE DECAY OF THE LAW OF CUSTOM.

THE progressive penetration of the white race into regions of the earth which are inhabited by coloured races may be said to have culminated in the recent expedition to Lhassa, which probably marks the beginning of a sapping process destined ultimately to lead to the fall of the last citadel of immemorial custom and prejudice. Under the title of the Decay of the Law of Custom an interesting address was recently delivered at the forty-fourth annual meeting of the Devonshire Association by the President, Mr. Basil H. Thomson, Governor of the Dartmoor Convict Prison. The laws of custom which have governed the coloured races for countless generations are, it is pointed out, gradually breaking down, though it is estimated that some 800,000,000 of the 1,500,000,000 constituting the population of the globe are still comparatively uncivilised and stagnant under the influence of these laws. The ever increasing facilities of intercommunication must make steadily for a greater uniformity of view and conduct amongst the different races of mankind and for the white race the question is of the first importance as to what part the coloured races will come to play in the affairs of the world when they shall have assimilated the teachings of Western civilisation. With this is bound up the question of the relative mental capacity of the white and coloured peoples. It would be rash to assert that any race is inferior in mental endowment to, and inherently incapable of reaching the mental level of, another, though plenty of white men are to be found who, after years of residence in Africa or the East, speak confidently of the general mental inferiority of the coloured races. Even in instances in which it is manifest that no such inferiority exists there is, they say, and always will be a profound difference between coloured and white races in the manner of viewing things. This is to maintain that a man's attitude of mind is as innate and as little liable to alteration as is the colour of his skin. We prefer to take the view that the differences between white and coloured races are in the main matters of custom and tradition and as such are subject to the influences of the agents of civilisation, such as steam and electricity, which have already done so much towards obliterating lines of demarcation between nationalities and towards establishing uniformity in manners and customs. That this is Mr. Basil Thomson's view may be seen from the following words of the address referred to:—"In tropical countries the line of caste would soon cease to be the colour of the skin. There, as in temperate zones, wealth would create a new aristocracy recruited from men of every shade of colour. In the great cities of Europe and America we might find men of Hindu, Chinese, and Arab origin controlling industries with their wealth just as Europeans now controlled the commerce of India and China, but with this difference, that they would wear the dress and speak the language which would gradually have become common to the whole commercial world. ...... Just as the aristocracy of every land would be composed of every shade of colour so would the masses of men who work with their hands. ...... White men would work cheek by jowl with black and feel no degradation. There would be the same feverish pursuit of wealth but all races would participate in it instead of a favoured few."

CHILDREN'S LIVES AND FLANNELETTE.

At the risk of its being considered vain repetition, attention should be called from time to time to the numerous lives of children sacrificed to flannelette. This sacrifice is offered more frequently among the poor than among those able to obtain helpers, for the mother who is single-handed cannot keep so close a watch on the children as her more fortunate sisters can arrange for. The coroner for Warrington, Mr. S. Brighouse, has held several inquests on these cases; one of the last was held on August 15th. The story seldom varies much. Here the little girl of eight years was left in the kitchen in her flannelette nightgown while the mother put the baby to bed. The child was reaching a roasted apple from the grate and her nightgown caught fire. She ran screaming into the yard and though the mother put out the flames the child died soon afterwards. The coroner said that "if parents wanted to lose their children a very easy way was to put them in flannelette and leave the kitchen fire without a guard." As some forms of this material are so inflammable and as it can, so it is stated, be readily rendered so little inflammable as to be a practically safe material, it is much to be desired that this fire-proofing process should be made compulsory.

CONGENITAL WORD BLINDNESS.

To the *Ophthalmoscope* for August Dr. C. J. Thomas has contributed an important paper on congenital word blindness —a condition to which attention has been directed by ophthalmic surgeons only in recent years but which appears to be far from uncommon. Since the London County Council issued an instruction to head teachers to submit to the medical officer every child of the age of seven years who appears very backward or defective a great number of cases of word blindness have been brought to light. Dr. Thomas calculates that nearly 1 in 2000 of London elementary school children has word blindness to a considerable degree. It seems to be most frequent in the lower classes and, like the allied conditions of idioglossia, amusia, and congenital word deafness, frequently assumes a family type. It occurs much more often in boys than in girls. The following is an example. A boy, aged seven years, was admitted to a special class in 1901. He was clever in all handiwork and had good powers of observation and reasoning but could not remember how to make the letters. In 1904 he was bright and intelligent and could do difficult sums in mental arithmetic but all attempts to teach him to read had failed. But he could read Arabic numerals and do sums in multiplication. He said that the written word "not" stood for "one"; "buds" he read as "branch"; and "horse" he could not read (he mistook "r" for "b"). But he recognised all these words when spelt aloud. His desire to read was painful, for he was more than ordinarily ambitious. In 1905 he could with difficulty make out a few words of three letters, which he did by tracing them out with his finger, thus utilising a form of kinæsthetic memory. In less serious or partial cases if the child is intelligent other centres in the brain may be used as a help and the child may pass muster but not become a fluent reader. Dr. Thomas refers to a case in which the child was of brilliant capacity and became an excellent surgeon. He practically did no reading but acquired all his knowledge at lectures and classes. The treatment consists in placing the child in a special class in which he can receive individual attention. The initial difficulty in learning the letters is due to the fact that the 26 signs are too numerous to be learnt and retained unless used in word-building. On the other hand, as Dr. James Hinshelwood has pointed out, the recognition of Arabic numerals is readily acquired. Letters should be taught from large signs and the child should be encouraged to copy them. The ordinary individual recognises words as a whole without troubling to recognise individually the letters of which they are composed. His visual word centre is therefore stored with memories of words. Dr. Thomas recommends for word-blind children the phonic method of teaching elaborated by Miss Dale of the High School, Wimbledon, which ignores in the early stage visual word images. In this the child associates from the beginning the form of each letter with the mechanism for producing the most usual sound for which it stands. Thus each word is pronounced without calling upon the visual word centre at all and its meaning is arrived at from speech and auditory memories. Miss Dale has devised a series of reading books in which only regularly phonetic words are met until the child is considerably advanced. Then other memories may be invoked.

THE CHOLERA.

The following notice has been sent out by the Local Government Board for Scotland to the clerks to the various local authorities :—

Sir,—I am directed by the Local Government Board to state that cases of cholera have recently occurred in certain places on the shores of the Baltic Sea. Cholera was present in several localities in Eastern Europe in 1904, and it has since spread through Russia and has reached the Baltic by way of the River Vistula in the persons of raftsmen descending that river.

The cases which up to the present have occurred in East and West Prussia are therefore regarded as imported cases and no definite outbreak of the disease has been reported from any quarter of Western Europe. Under the circumstances mentioned, however, the ports of the Baltic and perhaps some of those of the North Sea must be looked upon as threatened with the disease, and the authorities of British ports trading with Baltic and North Sea ports should therefore be on their guard against the importation of cholera into their districts by means of vessels coming from such ports.

In the event of any port of the Baltic or North Sea being declared definitely infected with cholera it will be the duty of the local authority to take, with regard to vessels arriving from that port, the action prescribed by the Board's Cholera Order of the 1st January, 1893.

I am, Sir, your obedient servant,
G. Falconar-Stewart, Secretary.

The Clerk to the Local Authority.

It is an enormous tribute to the efficacy of the sanitary arrangements of the sea-ports of Great Britain that the approach of epidemic diseases from abroad, in spite of our commercial communications with all parts of the world, has no terrors for the community.

THE TREATMENT OF LEUKÆMIA BY THE X RAYS.

Recently several cases have been reported in foreign journals of great improvement produced in leukæmia by the use of the x rays but the final results cannot yet be stated and therefore the value of the treatment remains to be appraised. In the July number of *Clinical Studies* Dr. Byrom Bramwell has reported two cases which are an important contribution to the subject. In one the patient was a boy, aged 15 years, suffering from lymphatic leukæmia. The mucous membranes were markedly pale and there were extravasations of blood around the eyes. The lymphatic glands were much enlarged and the spleen filled the left side of the abdomen. The red corpuscles numbered 2,000,000 and the white 340,000 per cubic millimetre and the hæmoglobin amounted to 38 per cent. A differential count gave small lymphocytes, 69·2 per cent.; large lymphocytes, 23·8 per cent.; polymorphonuclears, 4·6 per cent.; and myelocytes, 2·4 per cent. There were double optic neuritis and retinal hæmorrhages. In the second case the patient was a woman, aged 28 years, who was suffering from spleno-medullary leukæmia. She was not markedly anæmic; the spleen extended two and a half inches to the right of the umbilicus and almost into the pelvis. The lymphatic glands were not enlarged and the fundi were normal. The red corpuscles numbered 3,800,000, and the white 540,000 per cubic millimetre, and the hæmoglobin amounted to 69 per cent. A differential count gave myelocytes, 43·2 per cent.; polymorphonuclears, 41·4 per cent.; lymphocytes, 4·4 per cent.; eosinophile myelocytes, 5·8 per cent.; eosinophile polymorphonuclears, 2 per cent; and basophiles, 3·2 per cent. Both patients were treated by the application of the x rays over the spleen for five minutes, at first every other day and then every day. In both cases the temperature rose and assumed a swinging type. In the boy's case the treatment was commenced on Feb. 27th, 1905, when the red corpuscles numbered 1,600,000 and the white 230,000 per cubic millimetre and the hæmoglobin amounted to 33 per cent. On March 15th the white corpuscles had fallen to 7000, the spleen had considerably diminished, and the lymphatic glands were smaller and softer. But the red corpuscles did not increase in number and the general condition did not improve. On March 23rd the treatment had to be discontinued because of an erythematous inflammation produced over the enlarged spleen. Hæmorrhages from the gums and the nose occurred. On April 7th the red corpuscles had fallen to 660,000 per cubic millimetre and the hæmoglobin to 20 per cent.; the white corpuscles numbered 26,000 per cubic millimetre. Death occurred on April 15th. The result shows that in lymphatic leukæmia diminution in the size of the spleen and lymphatic glands and in the number of leucocytes is of no value if the red corpuscles and the amount of hæmoglobin do not increase. In the woman's case treatment was commenced on Feb. 28th. The white corpuscles steadily decreased and on June 7th had fallen to 12,000, the spleen much diminished, and the red corpuscles and hæmoglobin increased. On June 7th the patient menstruated for the first time for 11 months. Of the benefit derived from the x ray treatment there could be no doubt. It should be mentioned that both patients were given arsenic. These results are in accord with previous observations that the x ray treatment is more frequently beneficial in spleno-medullary than in lymphatic leukæmia. In some cases the rays were applied over the bones, in the marrow of which the lesion is supposed to be situated in the spleno-medullary form. It should be borne in mind that the use of the x rays is not without danger. An American writer, Dr. Dock, states that in some cases death has occurred during, and possibly as a result of, the treatment.

MEDICAL PRACTICE IN PERSIA.

THE unwillingness of Asiatics to adopt the habits and customs of European nations affects their appreciation of medical practice as conducted by the foreigners who come among them. In no countries are innovations imported from abroad welcomed on their first introduction and in the East it is generally found necessary to make some concession to local prejudices, though in important medical questions such compromises are nearly impossible. In Persia, where medical practitioners, male and female, have for years been labouring on behalf of the Church Missionary Society and other Christian agencies, it is said that native opinion is on the side of the native practitioners as regards purely medical treatment, but the superiority of the foreign surgeons over the hakims is admitted. Persian surgery unquestionably has its weak points. Violent taxis is the rule in herniæ; in cases of cataract eyes are frequently spoiled by dislocation of the lens backwards; trichiasis is sometimes improved by the unsightly method of causing sloughing of part of the offending id—usually by ligature. A great field is therefore open for European philanthropy in Persia where the agents of the Church Missionary Society have two hospitals—one with 48 beds in Julfa, the Armenian suburb of the old capital Ispahan, and one with 21 beds in Kerman, the chief town of the large province bearing the same name. In the hospital at Julfa in 1904 there were 1079 in-patients admitted (202 medical and 877 surgical cases), 547 major and 1138 minor operations were performed, and 11,790 new out-patients were treated. In the hospital at Kerman during the same period 217 in patients were admitted, 211 major operations were performed, and 4276 new out-patients were treated.

LUNACY IN EGYPT.

THE lunacy problem in Egypt seems to be assuming a degree of importance which demands the attention of the Egyptian Government. In the ninth annual report of the Egyptian Government Hospital for the Insane, Cairo, for the year 1903, the medical director, Dr. John Warnock, states that "during the year 1903 the 500 beds of the hospital have accommodated over 1000 patients, of whom more than 500 were admitted during the year." The rate of lunacy continues to increase and "the number of admissions would have been much greater if steps had not been taken to prevent the reception of any but dangerous or unmanageable lunatics." With the present limited accommodation and the increasing pressure of new cases demanding admission certain patients of the asylum have from time to time to be discharged prematurely, with the result that recovery is not completed in their own homes and many of them "return after a varying interval ill-treated, excited, and unmanageable, often also suffering from injuries." The problem of dealing with the increasing lunacy seems to be both difficult and serious. With the object of reducing the number of admissions, says Dr. Warnock, Government medical officers are instructed only to certify cases which they consider to be dangerous; the result of this limitation has been that several cases which medical officers have declined to certify have been taken to the asylum as criminal lunatics later owing to their having committed some criminal offence. A recent modification of the instructions has been made which it is hoped will prevent such occurrences. The discharge of dangerous lunatics who had partially recovered having resulted in acts of murder or of attempted murder by some of them while at large or while in the care of relatives, such cases are now retained longer in the asylum, with the result that in a few months the asylum population has risen to 100 more than the buildings should hold and overcrowding exists. 67 alleged criminal lunatics were examined during the year and 59 were admitted. "The number of these cases shows a large increase on past years. 16 of them had formerly been inmates here and most of them had been discharged for want of accommodation." The construction of an annexe at Abbasia to accommodate patients of this class is proposed by Dr. Warnock as a satisfactory arrangement helping to meet the requirements of criminal lunacy in Egypt. It is also advised that the existing asylum buildings and grounds at Cairo should be extended and a criminal annexe built, "as the present distribution of the criminal lunatics is most unsatisfactory, half of them being here [at Cairo Asylum] and the rest at Tourah, where they are too distant to allow of our constant observation of them." The extensions proposed would suffice to accommodate 140 male criminal patients, 205 ordinary male patients, and 50 female patients. While the existing asylum with its extensions would continue sufficient to provide for Upper Egypt and Cairo, Dr. Warnock is of opinion that a new asylum should be provided without delay for cases occurring in the Lower Egypt provinces and towns. A convenient site for it might be found, he says, near Alexandria, where cases from all parts could be easily brough by rail. "The more northerly the site the cooler the summer climate and the more suitable for the treatment of lunatics, when the heat causes much excitement and irritability." The buildings at the Cairo Asylum have been better supplied with water during the year, a high-pressure tank in the tower being kept constantly full, while the means of protection against fire have been improved. The drainage and sewerage systems have also been rendered more efficient. The daily average number of patients resident during the year 1904 was 512. The admissions during the year amounted to 495, comprising 383 males and 112 females, showing a slight decrease from the year 1903. The cost of maintenance has been high during the year owing to an increase in the price of meat, milk, and provisions. The institution is under the charge of Dr. Warnock, and a deputy superintendent, assisted by three native Egyptian medical men. Mechanical restraint is practically never used, though seclusion has to be employed daily (on an average of six cases). Of the forms of insanity in the admissions 40 per cent. were maniacal or depressive cases, 7 per cent. were cases of general paralysis, 10 per cent. of pellagrous insanity, 18 per cent. of hasheesh insanity (maniacal, delirious, depressive, acute toxic, and demented forms), and the rest were of other forms. Of the causes of insanity in the admissions, hasheesh accounts for 74 out of 495 cases, pellagra for 52 cases, syphilis for 23, worry and poverty for 23, senile decay for 17, congenital mental defect for 14, alcohol for 12, epilepsy for 12, and other causes for the rest. The deaths during the year amounted to 79—viz., 60 males and 19 females. Of the deaths, seven were due to senile decay, eight to pulmonary and other forms of tuberculosis, ten to pellagra, 18 to general paralysis of the insane, and the rest to other causes. Half of the tuberculous deaths were of patients who were already suffering from the disease on admission. During the present year a villa for the reception of male patients of the private class will be completed.

GEORGE CRABBE, DOCTOR, POET, AND PARSON.

FEW persons nowadays read the poems of the Rev. George Crabbe and of those who do, most probably derive their first knowledge of them through the medium of the delightful "Rejected Address," commencing—

> "'Tis sweet to see from half-past five to six
> Our long wax candles with short cotton wicks,
> Touched by the lamplighter's Promethean art,
> Start into light and make the lighter start."

Fewer persons still know that Crabbe was originally brought up to be a medical man, being in 1768 bound apprentice to a village practitioner a few miles from Bury St. Edmunds, by whom he was at first employed as errand boy and labourer on the land, this being the usual way to treat the medical apprentice in the country 130 years ago. About 1774 Crabbe's father sent him to London to pick up a little surgical knowledge. He then returned to Aldeburgh, the little seaside Suffolk town where he was born, and became assistant to a surgeon, afterwards setting up in practice for himself. The practice, however, was not very successful and Crabbe came to London to try his hand at literature. Here the success of the "Library," the whole profits of which were generously given to the author by his publisher, brought him fame. He then took holy orders, being ordained in 1781. He was at first assistant curate at Aldeburgh and afterwards held various small livings in different parts of England. Like many another parish clergyman, he gave medical advice to the poor of his parish, being justified, as many of them are not, in that he had had a medical training. We are led to these remarks by having received a notification of a celebration to be held at Aldeburgh from Sept. 16th to 18th in commemoration of the 150th anniversary of Crabbe's birth. The items of the celebration include a reception by the Mayor of Aldeburgh, a visit to the parish church, in which will be shown the vestry books proving that Crabbe acted as parish medical officer in 1775, and besides these there will be an exhibition at the Moot Hall of relics connected with Crabbe, such as manuscripts, pictures, and engravings. Papers will be read during the meeting, among them being one by M. Huchon, professor at the University of Nancy, on "Crabbe's Aldeburgh," and another by Mr. Clement Shorter on "Crabbe's Place in English Literature." Visits will also be paid to places in the neighbourhood where Crabbe executed various clerical duties.

THE PREVALENCE OF EPIDEMIC PARALYSIS IN SWEDEN.

IN its issue of August 22nd the Stockholm *Svenska Dagbladet* states that about a month previously an epidemic nervous disorder appeared in certain parishes of the district of Skaraborg and that Dr. Ernest Levin was sent by the medical board to Vestergötland for the purpose of making inquiries as to its nature and origin. The first case was observed on July 10th in the parish of Trästena. During the nine succeeding days 13 new cases were announced at Trästena and Hjälta and during the next ten days 17 fresh cases. The disease had then attacked in almost equal numbers all ages from one year to nine years. After July 30th it seemed as if the epidemic were decreasing, but in the meanwhile it appeared in Mariestad where 12 cases occurred up to August 1st, after which it seemed as if the epidemic had ceased also in the last-named place. Unfortunately, however, it was soon evident that the disease was not confined to Vestergötland, for it appeared in other parts of Sweden widely remote from each other. The first report of it from Hernösand came on August 9th. The medical officer at the hospital there had on the same day no less than three cases of acute poliomyelitis, two of them from the same parish, Ullanger, and three weeks previously a patient had died after being ill for only three days. Almost at the same time a report was received from a medical man in Valdemarsvik that some remarkable cases of sickness had happened amongst children in the district. The first symptoms were said to be feverishness followed by slight paralysis and there was therefore a danger that in the present circumstances the disease would be diagnosed as acute infantile paralysis. The medical board ordered that the schools should be closed where necessary and that all precautions usual during the prevalence of an epidemic should be observed. At the same time the medical board informed the provincial governments of Ostergötland and Vesternorrland that if it were necessary to send additional practitioners to the infected districts their expenses would be paid by the State, just as in the case of dangerous epidemics. Two days after the announcement of the epidemic in Valdemarsvik and Hernösand a newspaper in Smaland stated that an infectious disease of children had been prevailing for several weeks in the district of Kronoberg, although its existence had only just come to the knowledge of the local practitioners. The symptoms were violent headache, high fever, relaxation of the muscular system, and spasmodic twitchings. It attacked children of all ages and even adults up to the age of 27 years, the latter being apparently more severely affected than the younger sufferers. In some cases death had ensued after only a couple of days. Dr. Levin informed a representative of the *Svenska Dagbladet* that the disease differed in many respects from acute infantile paralysis. As a rule it did not attack very young children but was more prevalent among adolescents, the upper limit of age being 20 or 21 years. It was often fatal and in such cases the course was so rapid that a patient might die on the first day of the illness. When the febrile stage had subsided it might be followed by paralysis of the arms and legs. In some of the patients the paralysis seemed to be permanent and in others it had partially or entirely disappeared; but there were cases, and not a few, where the whole of the beginning of the course of the disease exactly resembled the above named cases yet without the occurrence of any paralysis whatever. During the febrile stage the temperature is usually between 38·5° and 39·5°C. and the patient, as a rule, exhibits extreme tenderness in the muscles of the back, neck, and shoulders, as well as stiffness and rigidity of the neck. The sensibility is often so great that the patient screams at the least movement of the muscles controlling the parts just named. It does not seem that any state of coma occurs during the last stage of the disease and when the case ends in death full consciousness is usually maintained to the last. Various methods of treatment have been followed but with little apparent benefit. Isolation of the patient is essential for the purpose of checking the spread of the disease. The remarks attributed to Dr. Levin give no information as to any points of resemblance or difference between the disease in question and the epidemic of cerebro-spinal fever which has existed in Central Europe since the latter part of 1904.

THE BAWDEN FUND.

Mr. Edgar Speyer, the well-known banker, has been made the almoner of a munificent philanthropist—namely, Mr. E. G. Bawden of the Stock Exchange. In a letter communicated to the press Mr. Speyer says that Mr. Bawden has intrusted him with the sum of about £100,000 "to be applied to purposes of charity and benevolence and for the advancement of knowledge, especially in aid of human suffering." With the concurrence of the donor Mr. Speyer has decided to apportion the money to various institutions in the form of capital to be vested in trustees, to be known in each case as the "Bawden Fund." The sum of £16,000 is allotted to complete the sum of £200,000 to bring about the incorporation of University College in the University of London; £10,000 are allotted for East-end emigration; £31,500 are divided between King Edward's Hospital Fund and ten of the metropolitan hospitals; while much of the remainder of the money is allotted to sundry convalescent homes, holiday funds, and various institutions for homeless and crippled children. Mr. Speyer's selection is, we think, a very good one. He has placed a large part of Mr. Bawden's grand gift in places where it will relieve the maximum of human suffering. All honour to Mr. Bawden for his noble gift; may it be the precursor of others from those who are blessed with this world's goods.

RADIO-ACTIVITY IN MINERAL PURGATIVE WATERS.

THERE appears to be little doubt that radio-activity plays an important rôle in the therapeutics of mineral waters and this may possibly account for the more favourable action of natural mineral waters compared with that of waters artificially compounded. In many instances it is difficult to explain the therapeutic value of a water merely upon its mineral constituents. Many waters are of distinct value, although analysis shows that very little mineral matter enters into their composition. The waters at Bath, Buxton, Contrexeville, and Wildbad, may be quoted as examples. These waters are distinguished, however, by being radio-active and in the gases evolved in certain of them helium, which may be regarded as a product of radium, has been found. In a paper read before the Royal Hungarian Society for Natural Science by M. Béla Szilárd some interesting results are recorded concerning the radio-activity of a mineral water known as Igmandi Bitter Water. The springs from which this water is taken are situated in the commune of Igmand, some two hours journey from Komarom. The water has been exported to this country under the name of "Bitter Purgative Water (Lord Roberts label)." The wells are situated on clay soil. The mud raised from the bottom of one of the wells proved to be considerably radio-active. Further inspection of the mud showed the presence of crystals which proved to be chiefly calcium sulphate. On testing the cleavage surfaces of these crystals for radio-activity such strong impressions were obtained and the entire plate was so fogged by the emanations that it was considered worth while to make quantitative measurement of the radiating energy. The effects are sufficiently marked to show on a reproduction of the photograph. Measurements were subsequently obtained leaving no doubt of the remarkable radio-activity of the calcium sulphate crystals. Crystals of the same substance obtained from other sources gave negative results. Next the bitter water itself was examined. The salts obtained by evaporation, after being thoroughly dried, were placed upon very thin black paper in a perfectly dark room upon highly sensitised plates. The plates were placed in a double light-proof box which contained also a porcelain cup filled with anhydrous chloride of calcium to keep the salts dry. After three weeks the plates were developed and in the case of the salts obtained from Igmandi Bitter Water showed strong radio-active effects. There were spots which were not uniform but of various dimensions, some larger, some smaller, some lighter, some darker, apparently in accordance with the shape of the dry crystals and the nature of the contact. It is evident from this research that the Igmandi Bitter Water is decidedly radio-active, the activity being characterised chiefly by emanations. The radio-activity of the water is doubtless derived from the salts in solution, amongst which is calcium sulphate. Even in bottle the radio-activity is preserved for a considerable time. It will be interesting to learn how far radio-activity influences the therapeutic action of the purgative salts. According to recent researches the influence of radio-activity in this connexion would appear to be favourable.

UNTRAINED MIDWIVES.

AN important inquest was held recently at Kingston on the death after childbirth of a woman who had been attended by a midwife. A charge of neglect being brought against the midwife she said that she had been in practice as a midwife for 45 years, gave her age as 65 or 66, and further stated that she was certificated. The baby was born at 9 o'clock at night and, according to the midwife's own admission, there was considerable neglect of the mother. On being questioned by the coroner as to whether she knew how to take the temperature she replied that she did, she did not know the normal temperature of the body and had no thermometer. She was further asked if she understood how to stop bleeding and replied No, but that she would send for a medical man. The jury came to the conclusion that there had been neglect on the part of the midwife and were of opinion that a woman of her age should not be allowed to practise midwifery, for they believed she was much older than she stated herself to be. They further recommended that the case should be reported to the Central Midwives Board. When the new Midwives Act was introduced it was a matter of great difficulty to know what to do with the large number of women who were practising all over the country as midwives and who had never obtained a certificate in midwifery from any recognised institution. It would have been a great hardship to these women if their means of livelihood had been taken away and it was determined, therefore, that those of them who had been in *bonâ-fide* practice as midwives for 12 months previous to July 31st, 1902, should be permitted, on application being made to the Central Midwives Board, to have their names registered on the roll of midwives. In these conditions naturally a number of untrained and ignorant women are practising in various parts of the country as certificated midwives. As time goes on the number of these women will gradually diminish and their places will be taken by properly trained women who have passed the examinations of the Central Midwives Board. It is difficult to see how any other solution of the problem could have been arrived at without a grave injustice being done to certain competent midwives and without depriving the public of a form of necessary assistance. The Board has, of course, the power necessary to take off the roll the name of anyone who is found to be unfitted or who is convicted of negligence, and no doubt will do so in the case of the midwife in this instance if it finds the views of the coroner and his jury just.

THE BATHS AT HARROGATE.

AN important addition to the bathing facilities at Harrogate has recently been completed by the installation of the necessary appliances for the carrying out of the treatment which has hitherto been almost entirely associated with the French spa, Plombières-les-Bains. In THE LANCET of April 30th, 1904, p. 1186, we published a paper by Dr. de Langenhagen on the Treatment of Muco-membranous Colitis in which the methods adopted at Plombières are set forth in detail. Rectal irrigations when properly carried out are without doubt very valuable in the condition described by Dr. de Langenhagen and also in other diseases of the intestinal tract, such as catarrhal enteritis and intestinal lithiasis. The treatment has also been recommended for appendicitis and in cases of doubtful diagnosis a "hydro mineral cure" may often be tried with advantage. Dr. de Langenhagen is of opinion that the "intestinal bathing" should be considered as a real "internal dressing" of the mucous membrane, and he therefore claims that rectal irrigation is suitable not only in cases of colitis with constipation but also in those cases in which there are alternations of constipation and of diarrhœa or in cases of chronic diarrhœa. Many patients who cannot from financial or private circumstances proceed to a continental spa can and will go to one in England. This latest addition, then, to the baths of Harrogate is likely to prove a most useful one and the corporation of Harrogate may be congratulated on the enterprise which has just been completed.

CONGRESS OF THE INTERNATIONAL SOCIETY OF SURGERY.

AT the first Congress of the International Society of Surgery, which will be held in Brussels from Sept. 18th to 23rd, one of the subjects for discussion will be the Surgical Treatment of Non-Cancerous Affections of the Stomach. The discussion will be opened by Dr. A. Monprofit, professor of clinical surgery in the Medical School of Angers in France; Mr. A. W. Mayo Robson, Vice-President of the Royal College of Surgeons of England; Dr. J. Rotgans of Amsterdam; and Dr. A. Mattoli of Rome. From abstracts of the forthcoming addresses, published by the secretary of the Congress, it appears that Dr. Monprofit will include in his remarks the operations of puncture of the stomach through the abdominal wall, paragastric exploratory laparotomy, extragastric and intragastric dilatation of the pylorus, pyloroplasty, exploratory gastrotomy, gastrorrhaphy, curetting and cauterisation of gastric ulcers, gastrostomy, partial gastrectomy in various situations, gastroplasty, gastropexy, gastro-anastomosis, anagastrostomosis, total gastrectomy, and gastro-enterostomy. This last is the operation which he considers to be the most applicable in the majority of these diseases of the stomach. Mr. Mayo Robson will deal with the subjects of simple ulcer, hæmorrhage, adhesions of the stomach to adjoining organs or to the abdominal parietes, perforation, hour-glass contraction, tetany of gastric origin, dilatation, gastroptosis, acute phlegmonous gastritis, stenosis of the pylorus, injury of the stomach, hyperchlorhydria, and persistent gastralgia. Dr. Rotgans will confine himself entirely to gastric ulcer and its complications. He recommends operative treatment when the movements of the stomach are interfered with by conditions such as excessive peristalsis, vomiting, hypertrophy of the wall of the stomach, and retention of its contents. In such cases the cause is usually mechanical—namely, stricture of some part of the stomach or the existence of adhesions. The cause may also consist in *troubles dynamo-moteurs*, conditions in which the above-mentioned mechanical defects do not exist and gastroptosis is the only anatomical complication. He would also operate in cases of severe pain, tumours, hæmorrhage, perforation, and emaciation. Dr. Mattoli will discuss the surgical treatment of gastroptosis, pyloric stenosis, circular perforating ulcer, and several other gastric abnormalities. The official languages of the Congress are English, French, German, and Italian. During the proceedings a general meeting will be held to appoint the International Committee, to fix the next place of meeting, and to elect a president. We understand that the Belgian committee will send invitations to fêtes in honour of foreign members of the society on hearing from them. Intimations should be sent direct without delay to the general secretary, Dr. Depage, 75, Avenue Louise, Brussels.

THE SURGEON'S RESPONSIBILITY FOR THE DETAILS OF AN OPERATION.

A MODERN surgical operation in many instances demands on the part of the surgeon not only a high degree of manipulative dexterity but also in a considerable measure the power of organisation. The details of the preparation of the patient, of the dressings, instruments, ligatures, and so on, take up a good deal of time and require special knowledge, and it may be impossible for the really busy surgeon to attend personally to all these matters. It is true that of recent years with the gradual replacement of antisepsis by asepsis these details have been a good deal simplified, but the danger to the patient where asepsis is practised is all the greater if by chance any of the procedure is not carried out with scrupulous accuracy. Whether the surgeon looks after these things himself or is compelled from the pressure of work to intrust them to others there can be no question but that he must be held responsible in the case of any accident occurring. If he has any doubt as to the capability of his nurses then it is his duty to see that their work is properly supervised and checked. If he does not give clear and definite instructions—and whenever it is possible these should be written—then he is alone to blame if his orders are not executed in their entirety. In hospital practice it is obvious that much must be left to resident officers and nurses, but even here it is the duty of the surgeon to inquire from time to time into the manner in which these duties are performed. There is always a tendency on the part of the most conscientious man or woman, although inspired with the best intentions, to become a little careless in the performance of duties which are of the nature of a routine to be carried on quite without supervision. It would seem hardly necessary to call attention to such an obvious truth, but from time to time instances occur in which a surgeon, forgetting human fallibility, has trusted too much to others and has neglected to overlook properly their subordinate work, with disastrous results to the patient. A great responsibility rests upon every surgeon with regard to all, even the minutest, details of an operative procedure, no matter how impossible it may be for him actually to perform the work himself. This has been recognised by all writers on the subject, indeed, so much has been written about the surgeon's responsibility lately that we should not have thought it necessary any further to allude to it had not a case come to our knowledge recently in which the opposite view was honestly taken by an operating surgeon, who attributed the faulty manner in which certain details had been carried out to the default of a nurse. The nurse may have been incompetent, but that would make it all the more necessary for the surgeon to supervise every circumstance of the procedure before, during, and after the operation. It cannot be too strongly insisted upon that the surgeon, and the surgeon alone, is responsible for every detail of the care of the patients under his charge. It is a terrible blow to the surgeon to know that his well-devised and safe operation has totally failed because of the mistakes of an assistant, but that is the consequence of his responsibility and he cannot escape it.

A CLINICAL BLOOD TUBE.

THE examination of the blood for purposes of aiding diagnosis is becoming a much more frequent procedure than it was a few years back. The calculation of the number of corpuscles and the estimation of the hæmoglobin are both of considerable value in arriving at a conclusion in certain disorders of the blood. There has always been a difficulty, however, in sending samples of blood to a clinical laboratory for examination. Mr. Watkins Pitchgood, government bacteriologist at Pietermaritzburg, has forwarded to us a small piece of apparatus which he calls a "clinical blood tube" and which promises to overcome this difficulty. It consists of a tube containing a measured quantity of a diluting fluid which also prevents the coagulation of the blood added to it. There are also some small capillary tubes, each of which is capable of holding a column of blood equal to one-hundredth of the bulk of the diluting fluid. Consequently, when the blood and the fluid are mixed a 1 per cent. dilution of the blood results. All the tubes are conveniently packed in a metal case similar to those in which clinical thermometers are carried. The blood to be examined is collected in the capillary tube which when full is placed in the fluid contained in the larger tube. The latter is thoroughly shaken until the blood in the capillary tube has escaped and becomes uniformly diffused throughout the diluent. Numerous comparisons have been made between this method of preparing the blood for examination and the one usually employed with the Thoma-Zeiss apparatus. The results are perfectly satisfactory. We believe that the use of this little instrument will be found very valuable in forwarding samples of blood for examination and the amount of technique required is small.

BLACK SMOKE FROM RAILWAY ENGINES.

THE Salford corporation recently summoned the Lancashire and Yorkshire Railway Company for an alleged smoke nuisance. The case was heard on August 23rd and the company was fined 5*s*. and costs. Railway companies are great offenders in this way not only in Salford, where numerous complaints have been made by residents, but all over the country. The goods trains sin more grievously than the passenger trains, possibly in part because inferior coal is used but very frequently from bad stoking. As to the latter, the companies must be a good deal at the mercy of their servants, but if a sufficient watch were kept the special offenders would soon be discovered and could be dealt with. The solicitor who represented the company said that "the defendants desired to avoid the emission of black smoke so far as possible and they asked that [illegible]n should be given to them by the corporation of any further offence." These "intimations" might very well be given by the people who suffer without going through the corporation. If the companies are sincere in their contrition private complaints would be attended to, while if such complaints were disregarded at first their frequent repetition by numerous residents might lead to reform. Those who know Salford, and what may be called its normally high standard of smoke pollution, will understand that the black smoke from the engines must be black indeed and very offensive to lead to complaints from those who live habitually in an atmosphere so sooty and foul. Among the various factors rendering town life injurious smoke holds an important place and ought to be persistently fought as a "nuisance injurious to health." An old saying was that a coach and four could be driven through an Act of Parliament. Now the locomotive finds it an easy task, for under the Railway Clauses Consolidation Act the railway companies were to have their engines so constructed as to consume their own smoke. Apparently the requirement is a dead letter in this country. In Germany it appears that the Ministry of Commerce and Trade has instituted "travelling courses of instruction for firemen. ...... The interest shown in the instruction is constantly increasing and its value, based on the results obtained, is more and more appreciated." This refers to stationary boilers, and some instruction in their safe and economical management if followed in practice would do much to lessen the smoke nuisance, but the instruction might with advantage be extended to the management of locomotives, which are accountable for a considerable share in causing annoyance and damage of various kinds as they rush through the land.

A PROVINCIAL sessional meeting of the Royal Sanitary Institute will be held in the council chamber, Guildhall, York, on Saturday, Oct. 7th, at 11 A.M. A discussion will take place on Pure Milk-supply, to be opened by a paper by Mr. C. W. Sorensen of the White Rose Dairy Farm, York, and formerly chief dairy expert to the New Zealand Government, on Some Aspects of the Pure Milk Problem from Within. Mr. T. H. Appleton will also read a short paper on the New Earswick Model Cottages. The chair will be taken by Colonel J. Lane Notter, R.A.M.C. Tickets for admission of visitors may be had on application to Dr. E. M. Smith, Guildhall, York; or to Mr. E. White Wallis, Parkes Museum, Margaret-street, W.

THE Harben lectures will be delivered in the lecture room of the Royal Institute of Public Health, of which Lord Strathcona has been elected President, on Tuesday, Oct. 10th, Thursday, the 12th, and Tuesday, the 17th, by Professor Thomas Oliver, physician to the Royal Infirmary, Newcastle-upon-Tyne. The subject chosen is Some of the Maladies caused by the Air we Breathe in the Home, the Factory, and the Mine, including a description of Caisson Disease or Compressed Air Illness. The lectures are open to the public and all interested are cordially invited to be present.

THE death is announced of Dr. Thomas Herbert Littlejohn, medical officer of health of Hampstead, from heart failure due to an accidental overdose of sulphonal. The deceased, who was the son of Sir Henry Littlejohn, medical officer of health of Edinburgh, was only 38 years of age and was generally regarded as a very sound and capable sanitarian.

A SUM of £10,000 has been received by the honorary secretaries of King Edward's Hospital Fund for London. The sum, which is to be retained as capital, is part of a bequest left by the late Miss Marianne Frances Hasker to be devoted to charity at the discretion of her executors.

REPORTS OF THE COMMISSION ON SLEEPING SICKNESS OF THE ROYAL SOCIETY.[1]

THE report of the work of the Commission is by this volume brought up to Nov. 15th, 1904. The evidence brought forward shows (1) that sleeping sickness is at first a specific polyadenitis caused by the trypanosoma Gambiense; (2) that a constant lymphocytosis exists at all stages of the disease; (3) that sleeping sickness is the last stage of this disease and is invariably fatal; (4) that resistance of both men and monkeys varies greatly and acquired immunity is probable; (5) that the action of arsenic in vita on the trypanosoma Gambiense is partial; (6) that bacterial invasion, chiefly coccal, occurs in some cases in the very last days of the sleeping-sickness stage of the disease and therefore cannot determine the onset of this phase of the malady; (7) that in Uganda trypanosomes other than the trypanosoma Gambiense are pathogenic in animals; (8) that these differ entirely from trypanosoma Gambiense; (9) that one of these is probably identical with trypanosoma Brucei; and (10) that all trypanosomes are conveyed from the sick to the healthy by the tsetse fly, glossina palpalis, and not by other biting flies (stomoxys). In the sleeping sickness areas in Uganda from 50 to 75 per cent. of the inhabitants are in the stage of polyadenitis and are carrying on their ordinary work, and these infected people from the fact that they present no symptoms of illness are especially liable to infect "clean" fly belts and so bring about a spread of the disease. Recently the districts around Lake Albert and the source of the Nile have become infected and the presence or absence of glossina palpalis in Egypt becomes an important factor in determining the spread of the disease to the north along the shores of the Nile.

A feature in the morbid anatomy of sleeping sickness to which attention has not previously been directed is a curious condition found in the stomach. The condition is comparable with the petechial hæmorrhages met with under the endo- and epicardium of the heart in trypanosoma infections. The following points have been determined: 1. The lymphatic glands of every case of sleeping sickness are enlarged and the juice taken by puncture during life contains many active trypanosomes and also disintegrating forms. 2. The lymphatic glands of cases of so-called "trypanosoma fever" are enlarged and the juice taken by puncture during life contains active and disintegrating trypanosomes. 3. Lymphocytosis occurs in all cases of sleeping sickness. 4. The cells of the cerebro-spinal fluid of cases of sleeping sickness taken during life by lumbar puncture are lymphocytes and are more numerous in the late stages of the disease. 5. The gland juice in a certain proportion of cases in the last stage of the disease becomes infected by bacteria, especially diplo-streptococci. 6 Injection of a pure culture of diplo streptococci obtained from cases of sleeping sickness did not produce any alteration of temperature or other morbid sign in the healthy animal nor in the animal infected by trypanosomes, but at an early stage of the disease; in one monkey seriously ill at the time of injection a local suppuration was produced. 7. "Trypanosoma fever" would appear to be an early stage of the disease —sleeping sickness.

In regard to the report on Sleeping Sickness in the Nile Valley by Captain E. D. W. Greig, I.M.S., the general situation is that the disease is slowly spreading in the "fly belt" and will extend to its northern and southern limit. The fly belt does not extend into the Sudan and therefore the disease will not reach the Nile Valley in this direction, but as the glossina morsitans, a closely allied species to the glossina palpalis, exists in the Bahr-el-Ghazal province the possibility of the disease being carried by this fly must be regarded as probable.

Mr. E. G. Austin contributes a chapter on the Distribution of the Tsetse Fly, with a map showing the localities in the African continent where it is known to exist.

Lieutenant A. C. H. Gray, R.A.M.C., and Lieutenant F. M. G. Tulloch, R.A.M.C., give the result of their experiments in connexion with the multiplication of trypanosoma Gambiense in the alimentary canal of glossina palpalis. An enormous increase was observed in about 10 per cent. of the flies 24 hours after feeding, which continued at later periods up to 12 days in a total of 5·6 per cent. of them. The proportion of freshly caught flies in a sleeping sickness district (Entebbe) which contained trypanosomes was tested, when it was found that out of 200 flies examined two contained an enormous number of the parasites.

---

[1] Volume No. V. Continuation Report on Sleeping Sickness in Uganda. By Captain E. D. W. Greig, I.M.S., and Lieutenant A. C. H. Gray, R.A.M.C. London: Printed for His Majesty's Stationery Sons, St. Martin's-lane. Illustrated. Pp. 287.

THE INTERNATIONAL CONGRESS ON TUBERCULOSIS.

THE International Congress on Tuberculosis will be held in Paris from Oct. 2nd to 7th, under the presidency of Dr. Herard, Professor Chauveau and Professor Brouardel being vice-presidents. It will be divided into four sections, of which Sections 1, 2, and 3 will respectively deal with the Medical Pathology of Tuberculosis (*President*, Professor Bouchard), the Surgical Pathology of Tuberculosis (President, Professor Lannelongue), and the Prevention and Treatment of Tuberculosis in Children (President, Professor Grancher), while Section 4 will be separated into two subsections, of which one will consider the Prevention and Treatment of Tuberculosis in Adults (President, Professor L. Landouzy) and the other will be devoted to Social Hygiene (President, M. Paul Strauss). All the meetings will take place in the Grand Palais, Avenue d'Antin, Champs Élysées. The subjects for discussion in Section 1 will be (1) the Treatment of Lupus and (2) the Early Diagnosis of Tuberculosis. In Section 2 they will be (1) the Comparative Study of the Various Forms of Tuberculosis; (2) Ileo-cæcal Tuberculosis; (3) Surgical Intervention in Tuberculosis of the Meninges and Encephalon; and (4) Tuberculosis and Traumatism. In Section 3 there will be four subjects for discussion relating to tuberculosis in families and schools and to its treatment in seaside homes. In Section 4 the subjects will be (1) the Etiology of Tuberculosis; (2) Insurance; (3) Influence of Dispensaries and Sanatoriums in the Prevention of Tuberculosis; (4) Hygiene of Dwellings; (5) Tuberculosis among Workers in Shops and Factories, in the Army and in the Navy; and (6) Disinfection in Relation to Tuberculosis. An exhibition will be held at the Grand Palais in connexion with the Congress and will remain open to the public during the whole month of October; it will be arranged in four sections—Pathological, Industrial, Social, and Historical.

Ordinary members of the Congress paying a subscription of 25 francs are entitled to take part in the work of the meetings and to receive its publications; their wives, sisters, and children may be admitted as associate members on payment of a subscription of 10 francs but must not speak or vote at the meetings. Both ordinary and associate members may attend all the receptions and other festivities held in connexion with the Congress; they are also entitled to the reduction of fares granted by the various railway companies. Return tickets (London to Paris and back) available for 14 days will be granted by the South-Eastern and Chatham Company and by the London and Brighton Company at the following rates:—South-Eastern Railway, first class, 58*s.* 4*d.*, second class, 37*s.* 6d.; Brighton Railway, first class, 39*s.* 3*d.*, second class, 30*s.* 3*d.* Intending travellers by these routes should apply to the National Association for the Prevention of Consumption and other Forms of Tuberculosis, 20, Hanover-square, London, W. The receptions and other festivities will include a reception by M. Loubet, the President of the Republic, a reception at the Hôtel de Ville by the municipality, a soirée given by the President of the Congress, the opening ceremonial at the Grand Palais, the closing ceremonial in the Grand Amphithéâtre de la Sorbonne, a banquet, and a gala evening. Visits will be made to the sanatoriums of Bligny (Seine-et-Oise) and Angicourt (Oise), to the hospitals for consumptive children in Ormesson, Villiers, Noisy, and elsewhere, to the Boucicaut Hospital, to the Institut Pasteur, and to various other establishments directly connected with the treatment or prevention of tuberculosis. Ladies will be received by a ladies' committee which will arrange for them excursions in Paris and the neighbourhood. After the Congress journeys will be made by special trains to institutions at Mont-des-Oiseaux (Riviera), Durtol (Auvergne), Hauteville (Ain), La Motte-Beuvron (Sologne), Montigny (Nord), and elsewhere.

The official languages of the Congress are French, English, and German. Members wishing to make a communication in one of the four sections must previously, if in France, send an application to the president of the section, but if in another country the application must be sent to the president of the national committee. The President of the national committee for Great Britain is Sir William H. Broadbent, 84, Brook-street, London, W., and the secretary is Dr. J. J. Perkins, 20, Hanover-square, London, W. No communication is to be made at a meeting unless its text has previously been submitted to the bureau of the Congress and written permission obtained from the president of the section. Ten minutes are allowed for each communication. Subscriptions will be received up to Sept. 30th inclusive by M. Pierre Masson, the treasurer, at the offices of the Congress, 21, rue de l'École de Médecine, Paris, and only his receipt will be acknowledged on behalf of the Congress. For objects to be shown at the exhibition application should be made to the Commissariat-Général at the above address. On Oct. 1st the office of the Congress will be transferred to the Grand Palais, where the meetings will be held.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

City of Liverpool.—The population of this important city during 1904 was estimated at 723,430, a total which is still materially behind that of Glasgow which was estimated at 798,357. Had Parliament consented to the absorption by Liverpool of Bootle the population of the extended Liverpool would apparently have almost equalled that of Glasgow, and it would then have devolved upon Glasgow to apply for another extension scheme. Parliament, however, decided otherwise and the decision is likely to have a material effect upon future extension schemes. The birth-rate of Liverpool for 1904 was 33·5 per 1000 and the death-rate 21·9 per 1000. As regards the important subject of infantile mortality the rates for 1904 ranged from 133 per 1000 births in Abercrombie district to no fewer than 281 in Exchange district. Liverpool still remains one of the very few places in the United Kingdom in which cases of typhus fever occur, and during 1904 there were 97 cases with 25 deaths from this disease, the yearly deaths during the last nine years having been as follows: 24, 36, 23, 19, 13, 11, 14, 25, and 57. Pulmonary tuberculosis is notifiable in a voluntary sense in Liverpool and has been so since the beginning of 1901. During 1904 there were 1897 cases notified and of these 188 were duplicates. The deaths numbered 1481, so that it is probable that but few early cases suitable for sanatorium treatment were brought to the notice of the health authority. This is regrettable, more especially as there are, we believe, two sanatoriums for the people of Liverpool—one at Heswall for paupers and the other at Delamere Forest for the working classes. We are glad to see that the smoke nuisance continues to be attacked by the Liverpool health authorities and that in the campaign the steamers on the Mersey are not allowed to escape. It is true that the smoke which rises from the Mersey traffic sometimes lends to Liverpool as viewed from Birkenhead an almost Turneresque effect, but those who are not artists would prefer to see the outlines of the city more distinctly. In this direction it is satisfactory to learn that the inclusion of Garston in the city limits has resulted in a reduction of smoke from the several copper-rolling mills in that locality. Dr. E. W. Hope reports that since the introduction of carburetted water-gas into Liverpool, presumably in 1895, eight cases, with six deaths, of poisoning by this gas have occurred. As regards milk control, the Liverpool Corporation Act, 1900, confers special powers upon the authorities and by its provisions inspectors are able to visit the various railway stations and take samples of milk which have been sent in from outside the city boundaries. If the milk is found to be contaminated with tuberculosis the veterinary superintendent, accompanied by a representative of the medical officer of health, may examine all the cattle in the cowshed from which the sample in question was derived. These "foreign" cowsheds contrast, Dr. Hope tells us, very unfavourably with those within the city limits. He speaks well of the operations of the Act in so far as Liverpool is concerned but, as he points out, there is nothing whatever to prevent the milk which is refused by Liverpool from being sent to other parts of the country where there are no "milk clauses" in operation. Liverpool consumes some 30,000 gallons of milk daily and of this amount about 17,000 gallons are produced within the city and about 13,000 introduced from outside. With a view to the reduction of infantile diarrhœa the corporation of the city of Liverpool has provided four milk depôts for the production of sterilised and humanised milk and this milk is distributed through the agency of 44 milkshops situated in different parts of the city. Dr. Hope observes that these milk depôts have been objected to on the ground that they may tend to save the lives of the children of the very poor who are already overburdened with offspring and that the expenditure may add a twelfth of a penny to the rates! The statistics furnished in the report before us are worth quoting, although, as Dr. Hope admits, no very great importance should be attached to them alone. Out of 5850 infants coming very promiscuously to the depôts (not to the shops) at varied ages and in conditions of health below the average, the mortality was 89 per 1000 (? children brought) as against 196 per 1000 (? births) for the city as a whole, 133 to 138 for the best districts and 258 to 281 for the worst. Dr. Hope points out, too, that the rates for children not attending the depôt above referred to include a large number of breast-fed infants and that if these were excluded the advantages in favour of the depôt would be much increased. It appears, too, that there is much evidence from parents, medical men, and others as to the value of these depôts and perhaps this testimony is more convincing than the statistics. All those interested in milk depôts should read this part of Dr. Hope's valuable report.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8646 births and 5188 deaths were registered during the week ending August 26th. The annual rate of mortality in these towns, which had been 17·0, 17·5, and 17·4 per 1000 in the three preceding weeks, declined to 17·3 per 1000. In London the death-rate was 16 7 per 1000, while it averaged 17·6 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 5 5 in Hastings, 6·8 in Hornsey and in Northampton, 8·2 in King's Norton, 9·2 in Burton-on-Trent, and 10·0 in Leyton; the highest rates were 23·3 in Merthyr Tydfil, 23·4 in Hanley, 23·9 in Great Yarmouth and in Middlesbrough, 24 8 in Salford, 25·9 in Rhondda, 26·2 in Burnley, and 29·8 in Grimsby. The 5188 deaths in these towns included 1580 which were referred to the principal infectious diseases, against 1507, 1626, and 1574 in the three preceding weeks; of these 1580 deaths, 1367 resulted from diarrhœa, 65 from whooping-cough, 53 from measles, 40 from scarlet fever, 33 from diphtheria, and 22 from "fever" (principally enteric), but not any from small-pox. The lowest death-rates from these diseases were recorded in Hornsey, Hastings, Brighton, Reading Devonport, Burton-on-Trent, Smethwick, Huddersfield, and Halifax; and the highest rates in West Ham, Wolverhampton, Grimsby, Stockport, St. Helens, Wigan, Burnley, Preston, Hull, Rhondda, and Merthyr Tydfil. The greatest proportional mortality from measles occurred in Barrow-in-Furness; from scarlet fever in Blackburn; from diphtheria in Middlesbrough; and from diarrhœa in West Ham, Wolverhampton, Grimsby, Stockport, St. Helens, Wigan, Burnley, Preston, Hull, Rhondda, and Merthyr Tydfil. The mortality from whooping-cough and from "fever" showed no marked excess in any of the large towns. No fatal cases of small-pox were registered either in London or in any of the large provincial towns, and no cases remained under treatment in the Metropolitan Asylums Hospitals on Saturday, August 26th. The number of scarlet fever cases in these hospitals and in the London Fever Hospital at the end of the week was 2762, against 2632, 2670, and 2735 at the end of the three preceding weeks; 343 new cases were admitted during the week, against 366, 355, and 361 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which were 111, 112 and 117 in the three preceding weeks, further rose to 118 in the week under notice and were 17 above the number in the corresponding period of last year. The causes of 41, or 0·8 per cent., of the deaths in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Leicester, Nottingham, Salford, Leeds, Newcastle-on-Tyne, and in 50 other smaller towns; the greatest proportions of uncertified deaths were registered in Portsmouth, Birmingham, Liverpool, Blackburn, Sheffield, and Sunderland.

In 76 of the largest English towns 8352 births and 5189 deaths were registered during the week ending Sept. 2nd. The annual rate of mortality in these towns, which had been 17·5, 17·4, and 17·3 per 1000 in the three preceding weeks, was again 17·3 per 1000 last week. In London the death-rate was 17·2 per 1000, while it averaged 17·4 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 4·3 in Hornsey, 8·0 in Burton-on-Trent, 8·2 in King's Norton, 8 4 in Handsworth (Staffs.), 9·2 in West Bromwich, 10·0 in Smethwick, 10·1 in Reading, and 11·0 in Bournemouth; the highest rates were 21·4 in Bury, 21·6 in Salford, 22·1 in Preston, 22·4 in Liverpool, 22·6 in Manchester, 25·2 in Grimsby, 25·8 in Hanley, and 26·6 in Sunderland. The 5189 deaths in these towns last week included 1432 which were referred to the principal infectious diseases, against 1626, 1574, and 1580 in the three preceding weeks; of these 1432 deaths 1189 resulted from diarrhœa, 73 from whooping-cough, 66 from measles, 44 from scarlet fever, 35 from diphtheria, and 25 from "fever" (principally enteric), but not any from small-pox. No death from any of these diseases was registered last week in Bournemouth; among the other towns the lowest death rates from the principal infectious diseases were recorded in Hornsey, Hastings, Reading, Devonport, Stockton-on-Tees, and Tynemouth, and the highest rates in Ipswich, Hanley, Wolverhampton, Walsall, Grimsby, Wigan, Bury, Burnley, Preston, York, Hull, and Sunderland. The greatest proportional mortality from measles occurred in Merthyr Tydfil and Swansea; from whooping-cough in West Hartlepool; and from diarrhœa in Ipswich, Hanley, Wolverhampton, Walsall, Grimsby, Wigan, Bury, Burnley, Preston, York, Hull, and Sunderland. The mortality from scarlet fever, from diphtheria, and from "fever" showed no marked excess in any of the large towns. No death from small-pox was registered last week in any of the large towns, and no case of this disease remained under treatment on Saturday, the 2nd inst., in the Metropolitan Asylums Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 2670, 2735, and 2762 at the end of the three preceding weeks, had further risen to 2873 at the end of last week; 427 new cases were admitted during the week, against 355, 361, and 343 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory organs, which had been 112, 117, and 118 in the three preceding weeks, further rose to 131 last week, and were 23 above the number in the corresponding period of last year. The causes of 37, or 0·7 per cent., of the deaths in the 76 towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Portsmouth, Bristol, Salford, Hull, Newcastle-on-Tyne, and in 46 other smaller towns; the largest proportions of uncertified deaths were registered in Northampton, Birmingham, Blackburn, Sheffield, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 14·8, 13·8, and 15·1 per 1000 in the three preceding weeks, declined again to 14·0 per 1000 during the week ending August 26th, and was 3·3 per 1000 below the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 11·1 in Greenock and 11·5 in Aberdeen to 15·9 in Dundee and 16·8 in Perth. The 471 deaths in these towns included 61 which were referred to diarrhœa, 18 to whooping-cough, nine to measles, two to scarlet fever, and one to "fever," but not any to small-pox or diphtheria. In all 91 deaths resulted from these principal infectious diseases, against 94, 67, and 74 in the three preceding weeks. These 91 deaths were equal to an annual rate of 2·7 per 1000, which was 2·6 per 1000 below the mean rate from the same diseases in the 76 large English towns. The fatal cases of diarrhœa, which had been 44 in each of the two preceding weeks, increased to 61, of which 34 occurred in Glasgow, ten in Edinburgh, five in Aberdeen, four in Dundee, four in Greenock, two in Paisley, and two in Leith. The deaths from whooping-cough, which had been 14, 10, and 16 in the three preceding weeks, further rose to 18, and included 11 in Glasgow and three in Paisley. The fatal cases of measles, which had been eight in each of the two preceding weeks, increased to nine, all of which were registered in Glasgow. The deaths from scarlet fever, which had been two, one, and one in the three preceding weeks, rose again to two during the week under notice, and both occurred in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 48, 33, and 41 in the three preceding weeks, further rose to 44, but were 11 below the number in the corresponding period of last year. The causes of 15, or more than 3 per cent., of the deaths registered in these eight towns were not certified.

The annual rate of mortality in eight of the principal Scotch towns, which had been 13·8, 15·1, and 14·0 per 1000 in the three preceding weeks, rose again to 14·8 per 1000 during the week ending Sept. 2nd, but was 2·5 per 1000 below the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 10·2 in Leith and 11·2 in Aberdeen to 15·7 in Glasgow and 17·2 in Dundee. The 496 deaths in these towns included 63 which were referred to diarrhœa, 14 to whooping-cough, seven to measles, six to diphtheria, four to "fever," and two to scarlet fever. In all, 96 deaths resulted from these principal infectious diseases last week, against 67, 74, and 91 in the three preceding weeks. These 96 deaths were equal to an annual rate of 2·9 per 1000, which was 1·9 per 1000 below the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of diarrhœa, which had been 44, 44, and 61 in the three preceding weeks, further rose last week to 63, of which 34 occurred in Glasgow, 11 in Edinburgh, 10 in Dundee, five in Aberdeen, and two in Greenock. The deaths from whooping-cough, which had been 10, 16, and 18, in the three preceding weeks, declined again to 14 last week, and included eight in Glasgow. The fatal cases of measles, which had been eight, eight, and nine in the three preceding weeks, fell last week to seven, of which six were registered in Glasgow. The deaths from diphtheria numbered six last week, against none in each of the two preceding weeks, and included three in Glasgow and 2 in Edinburgh. The fatal cases of "fever," which had been one, five, and one in the three preceding weeks, rose again last week to four, of which three occurred in Glasgow, one being a case of typhus. The deaths referred to diseases of the respiratory organs in these towns, which had been 33, 41, and 44 in the three preceding weeks, further rose last week to 53, and were identical with the number in the corresponding period of last year. The causes of 18, or nearly 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 21·2, 19·7, and 19·9 per 1000 in the three preceding weeks, declined again to 19·8 per 1000 during the week ending August 26th. During the previous four weeks the death-rate has averaged 20·2 per 1000, the rates during the same period being 16·7 in London and 14·4 in Edinburgh. The 144 deaths of persons belonging to Dublin registered during the week under notice were one fewer than the number in the preceding week and included 27 which were referred to the principal infectious diseases, against 29, 25, and 21 in the three preceding weeks; of these, 25 resulted from diarrhœa, one from measles, and one from diphtheria, but not any from small-pox, scarlet fever, whooping-cough, or "fever." These 27 deaths were equal to an annual rate of 3·7 per 1000, the death-rates from the principal infectious diseases being 5·0 in London and 2·0 in Edinburgh. The fatal cases of diarrhœa, which had been 25, 24, and 18 in the three preceding weeks, rose again during the week under notice to 25. The 144 deaths in Dublin included 43 of children under one year of age and 34 of persons aged 60 years and upwards;

the deaths of infants were slightly below the number in the preceding week, while those of elderly persons showed an excess. Six inquest cases and seven deaths from violence were registered; and 56, or nearly two fifths, of the deaths occurred in public institutions. The cause of one, or 0·7 per cent., of the deaths registered in Dublin during the week under notice was not certified.

The death-rate in Dublin, which had been 19·7, 19·9, and 19·8 per 1000 in the three preceeding weeks, rose again to 22·0 per 1000 during the week ending Sept. 2nd. During the past four weeks the death-rate has averaged 20·4 per 1000, the rates during the same period being 17·1 in London and 14·1 in Edinburgh. The 160 deaths of persons belonging to Dublin registered during the week under notice were 16 in excess of the number in the preceding week, and included 23 which were referred to the principal infectious diseases, against 25, 21, and 27 in the three preceding weeks; of these 19 resulted from diarrhœa, two from measles, one from diphtheria, and one from "fever," but not any from small-pox, from scarlet fever, or from whooping-cough. These 23 deaths were equal to an annual rate of 3·2 per 1000, the death-rates last week from the principal infectious diseases being 4·4 in London and 2·2 in Edinburgh. The fatal cases of diarrhœa, which had been 24, 18, and 25 in the three preceding weeks, declined again last week to 19. The 160 deaths in Dublin last week included 32 of children under one year of age and 41 of persons aged 60 years and upwards; the deaths of infants showed a decline from the number in the preceding week, while those of elderly persons was in excess. Four inquest cases and two deaths from violence were registered; and 51, or nearly one third, of the deaths occurred in public institutions. The causes of four, or 2·5 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons:—J. L. Thomas to the *Victory* and J. Sugrue to the *Excellent*. Staff Surgeons: W. B. Macleod, on recommissioning; W. M. Keith to the *Æolus*; R. D. Jameson to the *Eclipse*; G. R. MacMahon to the *Leander*; R. S. Bernard to the *Calypso*; F. Fedarb to the *Doris*; and E. R. Grazebrook to the *Arrogant*. Surgeons: F. R Featherstone to the *Renown*; G. Ross to the *Terrible*; C. J. Boucher to the *Woodlark*; M. T. Mate and G. H. S. Milln to the *Vivid*; J. E. Johnston to the *Arrogant*; J. H. Fergusson to the *Cambridge*, for the *Theseus*; A. G. Eastment to the *President*, for three months' course of hospital study; L. M. Morris to the *Impregnable*; B. Pick to the *Terrible*; A. C. W. Newport to the *Victory*; R. R. Fasson and W. G. M. Anderson to the *Leander*; A. Woollcombe to the *Psyche*; J. G. Peebles to the *Pandora*; J. St. J. Murphy to the *Eclipse*; and W. P. Walker to the *Racer*, for Osborne sick quarters.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel W. J Baker has been appointed officer in charge of the Military Hospital, Arthur Hill, Ireland. Captain T. J. Crean, V.C., has been appointed for duty with the troops of the London district. Captain W. M. Power has been transferred from the 6th (Poona) Division to the 5th (Mhow) Division. Brigade Surgeon J. Hector, retired pay, has been permitted to resign his post as medical officer in the London recruiting area. The Army Council has decided to cancel the order directing medical officers returning home at the end of a tour of service abroad to report themselves personally to the Director-General. These officers will in future report themselves to the War Office in writing. Lieutenant-Colonel J. Carmichael will embark for India in October. Captain T. H. M. Clarke, C.M.G., D.S.O., has been appointed for service in India (Eastern command).

Lieutenant D. D. Paton resigns his commission. Lieutenant-Colonel Arthur de C. Scanlan retires on retired pay.

The undermentioned gentlemen have been appointed Lieutenants on probation:—John Allan Anderson, Cuthbert Garrard Browne, Hugh Godwin Sherren, Henry Horace Andrews Emerson, Wallace Benson, Rowland Philip Lewis, George Edward Ferguson, James Herries Graham, Charles Ernest White Spinner Fawcett, Thomas Scatchard, Ronald Anderson Bryden, Arthur Edmund Stewart Irvine, Thomas Betteswortb Moriarty, Alexander Macgregor Rose, Edward Lawton Moss, Edward Guy Anthonisz, Griffith Henry Rees, Vivian Hood Symons, Walter John Weston, Mortimer John Cromie, Percy Farrant, Albert Edward Francis Hastings, George William Webb Ware, Michael Balfour Hutchison Ritchie, James Stuart Dunne, William McConaghy, Francis Cornelius Sampson, Charles Francis White, Cecil John Wyatt, Wilfrid Cowan Nimmo, Edmund Thurlow Potts, Michael Keane, Arthur Drought O'Carroll, Robertson Stewart Smyth, Arthur James Arch, Thomas Somers Blackwell, Harold Edgar Priestley, Alan Cunliffe Vidal, Philip Janvrin Marett, and Hugh Stewart.

The undermentioned lieutenants are seconded under the provisions of Article 349, Pay Warrant: Charles G. Browne, Percy Farrant, Cecil J. Wyatt, and Robertson S. Smyth.

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

Northern Command: Leeds Companies: Lieutenant A. E. L. Wear to be Captain.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain J. H. Stacy to be Surgeon-Major. Surgeon-Lieutenant-Colonel E. L. Freer, having resigned his commission in the Volunteers, ceases to belong to the Army Medical Reserve of Officers.

IMPERIAL YEOMANRY.

Pembroke: Surgeon-Lieutenant J. Wilson to be Surgeon-Captain.

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 2nd Middlesex: Surgeon-Captain and Honorary Surgeon-Major (Honorary Captain in the Army) A. Thorne to be Surgeon-Major.

Rifle: 2nd Volunteer Battalion the Durham Light Infantry: Surgeon-Lieutenant W. Bratton resigns his commission. 2nd Volunteer Battalion the Hampshire Regiment: Surgeon-Major (Surgeon-Lieutenant-Colonel, Army Medical Reserve of Officers) A. B. Wade to be Surgeon-Lieutenant-Colonel. 5th Volunteer Battalion the South Wales Borderers: Surgeon-Captain J. R. I. Raywood resigns his commission. 1st (Brecknockshire) Volunteer Battalion the South Wales Borderers: Surgeon-Captain D. Thomas to be Surgeon-Major. 1st (Exeter and South Devon) Volunteer Battalion the Devonshire Regiment: Surgeon-Lieutenant J. S. S. Perkins to be Surgeon-Captain. 1st Surrey (South London): Surgeon-Captain W. A. Atkinson to be Surgeon-Major.

THE AUSTRALIAN FORCES IN SOUTH AFRICA.

The following medical officers of the Australian military forces are granted temporary rank in the army whilst serving in South Africa:—To be Major: Andrew Honman, 2nd Contingent Victorian Mounted Rifles; and Walter Blake Nisbet, 4th Queensland Imperial Bushmen. To be Captain: James de Burgh Griffiths, 3rd Victorian (or Bushmen's) Contingent; Alfred Hobart Sturdee, 4th Victorian Contingent (Australian Imperial Regiment); Herbert Russell Nolan, 2nd Queensland Mounted Infantry; Albert Theophilus Duka, 3rd Queensland Mounted Infantry; Harold John Hutchens, 5th Queensland Imperial Bushmen; Edward Reginald Row, 6th Queensland Imperial Bushmen; John Tresselian Toll, 1st Contingent South Australian Infantry; George Frederick McWilliams, 1st West Australian Contingent; John Mitchell Young Stewart, 2nd Western Australian Contingent; Frederick John Ingoldby, 3rd Western Australian Contingent; Walter Gibson, 4th Western Australian Contingent; Joseph Ignatius Flynn, 5th West Australian Contingent; and Frederick Bentley Reid, 6th West Australian Contingent. To be Lieutenant: James Harold Patterson, 5th Contingent Victorian Mounted Rifles; Francis Charles Douglas, 3rd Contingent South Australian Bushmen: and Charles Mattei, 2nd Tasmanian Contingent.

DEATHS IN THE SERVICES.

Brigade Surgeon-Lieutenant-Colonel Mathew Moriarty Gallwey, late Royal Army Medical Corps, on August 30th, at 3, Suffolk-place, Pall Mall, London, S.W., aged 63 years. He entered the service as assistant surgeon in October, 1867, was promoted surgeon in March, 1873, surgeon-major in October, 1879, lieutenant-colonel in October, 1887, and brigade-surgeon-lieutenant-colonel in August, 1893, retiring in August, 1897.

AMBULANCE DOGS.

At the approaching review of volunteers in Edinburgh the ambulance service will include six dogs, trained by Major Richardson of Panbride, Carnoustie, for ambulance work in time of war. These animals have taken part in military manœuvres during the past two years. Last year they were at Stobs, and this year they were tried on several occasions with both the regulars and the volunteers at Buddon and Barry camps, and a few weeks ago they were in use in manœuvres in the South of England.

THE LATE WAR IN THE FAR EAST.

With the *signing* of the treaty of peace by the Russian and Japanese plenipotentiaries one of the biggest and most remarkable wars on record becomes a thing of the past. It is happily not for us to criticise the terms of the treaty or to dwell upon the political results which may be expected to follow. It is sufficient to say that, from a humanitarian point of view, the treaty puts an end to an enormous sacrifice of life. The history of the war in its medical and sanitary, as well as in its military, aspects has yet to be written. Meanwhile the main facts connected with its history—from the causes which gave rise to it and the momentous events which characterised its course up to the final act of signing the treaty which put a stop to it—are sufficiently well known. These facts speak for themselves and we cannot refrain from calling attention to them on account of the contrast exhibited between the very dignified but modest tone adopted by the Mikado in his telegram to President Roosevelt in appreciation of the latter's services and that shown by the Czar in the nature and tone of his address to the Russian army under General Linievitch.

The First Commissioner of Works, &c., with the concurrence of the Lords Commissioners of His Majesty's Treasury, has appointed Surgeon-Lieutenant-Colonel Charles Randolph Kilkelly, C.M.G., late Grenadier Guards, to be House Governor and Medical Superintendent of Osborne as from July 4th last. The First Commissioner of Works, &c., has appointed Dr. Edgar Hoffmeister a member of the consulting staff of Osborne.

Mr. M. F. Ellis, of Northern Nigeria, is mentioned in despatches from Colonel Lugard to the War Office in connexion with the expedition in West Africa. Mr. Ellis was one of the medical staff attached to the expedition.

Correspondence.

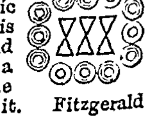
"Audi alteram partem."

PYGMIES.

To the Editors of THE LANCET.

SIRS,—Dr. G. Elliot Smith's "Notes on African Pygmies" in THE LANCET *of* August 12th, p. 425, is a most interesting and important contribution to our knowledge of these primitive little "earth men" and for those who take an interest in the origin of the human race, and I am pleased to see that his accurate measurements correspond with those I made in a "superficial" way and published in a short article, "A Study of the Pygmies," in the *Standard* of July 7th last. There are, however, one or two points that Dr. Smith has not touched upon but which, to gain an accurate idea of how much these little people are connected with the development of the human race, it is very important to know.

I have seen it stated that Sir Harry Johnston says these pygmies have no language of their own but all they speak are words that they have derived from surrounding tribes. I cannot agree with this; on the contrary, from an interview I have had with them I came to the conclusion that they have undoubtedly a monosyllabic language (they may also have acquired other words) and that this language was the first language of man, and that other tribes who have the same words have acquired the same from them. The proof of this lies in the old hieroglyphics of Egypt. Take some of the words I have already learnt and deciphered, as, for example[1], *mu a mai* water; *O-be* is *ānb*  to dance or to rejoice; *A-do-da* is *Ā x* or *z a*  to sleep: *Bacchate* is *baaq*  grain or fruit; *Massouri* is *Maāu*  good, right, straight, to do well, and many others; but the above are sufficient to show that these pygmies still use the first and oldest words that were to express in articulate form and sound their meaning of things—in what we call language. There is no doubt in my mind that the pygmy was the first man developed from the Pithecanthropos erectus or some form of this; probably the original was nearer allied than the present form of pygmies in London. The remains of this primitive race we find all over the world; from the sources of the Nile they spread north, south, east, and west over the world. The Veddas of Ceylon, the earliest race in Japan that the Anu drove out and exterminated, the earliest race in Australia before the "present aborigines," and the earliest race in Mexico—we find all the same. That these pygmies should have learnt the words and language that they still use from the ancient Egyptians is not conceivable, or could there be any argument to that, except that some remnant of the ancient Egyptians were driven south and had degenerated from a comparatively high state of civilisation to a prognathous type of pygmy and against such an argument their "sacred ceremonies" as they call them—of which their dance is a part—would be conclusive. When I drew the oldest hieroglyphic sign for Amsu  they recognised it immediately. (Dr. Smith agrees with all other authorities in stating how readily they recognise picture signs and draw them themselves and at the same time stating that the negroes do not.) All authorities have hitherto stated that they have no religious ceremonies; this is not correct, because when they danced at the Hippodrome in London they took off their ordinary headdress (a bunch of feathers or that to represent the same) and put on the representation of the "Horus lock," also the panther's skin with the tale hanging down behind, and they told me that this was part of their "sacred ceremonies." That they recognise the most ancient sign for Amsu or Horus I (which I drew and asked the chief Bohani if he knew what it was; he smiled and asked one standing by him to tell me; he pointed to his chief and spoke his name—that is him) is very important to Egyptologists and antiquarians, because it is the first sign used by primitive man as the chief or great one and it was used as the sign for the chief of the Nomes and is found depicted on the oldest Australian boomerangs and on the ivory tablets found in the tomb at Naquada, and I have found the same sign in other parts of the world on stones of the neolithic period. This sign, then, would have originated with the pygmies as the sign of their chief or their great one, and as evolution advanced we find that this sign was still used and carried on by the Nilotic negroes and used in the Totemic ceremonies. When the next exodus of men and women took place from this centre (Nile Valley) we find that they still carried and used this sign, but in a higher sense, until in the time of the predynastic Egyptians and the dynastic Egyptians it had then assumed the sign of Amsu or Horis I risen. The oldest god of all in Egypt was Bes , as is well shown in Budge's last book, "The Gods of the Egyptians," vol. ii., p. 286. And no one seeing this and the pygmies, even if he was not an Egyptologist, would fail to identify the two in form, figure, and dress. Bes here has the same type of face as the pygmies. The yellow plume of feathers (*La-gou-ma*) is worn on the head and exchanged for the "Horus lock" during the "sacred ceremonies," the green and yellow "dress" are also worn and the leopard skin with the tail hanging down behind (peculiar to the land of Punt). Bes therefore, who was afterwards represented as a type of Horus, was their "Chief of the Nomes," and it was from these pygmies that the first mythology sprang, and all has been brought on, added to, and made use of in the various types from the earliest myths to astronomical, stellar, lunar, and solar mythology, and finally the eschatology which we know so well. Maspero says: "It [the Land of the Shades beyond Punt] was inhabited by the Dangas, tribes of half savage dwarfs, whose grotesque faces and wild gestures reminded the Egyptians of the god Bes—*none knew better than they the dance of the god—that to which Bes gave way in his merry moments.*" The "Land of the Shades," as Maspero calls it, was the land of the spirits or Khui land; this was first mapped out on the celestial heavens and then in the lakes at the head of the Nile; and the hieroglyphic for the "Khui land," "a region of Amentu," Land of the Spirits or Gods, represented by six triangles with their apices joined and surrounded by concentric circles (three one way and three opposite) is found all over the world—in Australia and North America and in Ireland—and it is a significant fact that when I drew it the pygmies at the Hippodrome recognised it.



Fitzgerald

---

[1] These words are expressed phonetically, and as one cannot get the proper sound in English French is used.

Marrott also found it on the bodies, tattoed, of the West African negroes who belonged to the secret tribal societies. Dr. Smith noticed, I see, as well as myself, that only the chief was circumcised—an important and interesting fact connected with the "sacred ceremonies." As regards the two women not menstruating during the period they were under observation by Dr. Smith, this may be explained by the fact that one woman was past the climacteric period and the other, Kuarhe, was pregnant.

That the "Bushman" of South Africa is an offshoot and nearly allied to these pygmies is confirmed not only by the steatopygous condition and appearance of the younger woman but by other points—viz., the hair is the same character—"pepper-corns"—the "labium" is the same character in form, the large size of their teeth, their weapons are the same, and many other points. Their "sacred ceremonies" correspond—it is very difficult to get to the original rites of these; we must remember that all native tribes guard most jealously anything pertaining to their sacred ceremonies and often pretend not to understand. Spence and Gillam have proved this perhaps more than any other men in regard to the Australian aborigines. Maspero and other Egyptologists will not find the key to unlock the door of the past until they study and understand the primordial, then only shall they come to the truth, and find the alphabet so plainly written that they will wonder why they did not read what is written so plainly, that man originated in Africa at the sources of, and along the banks of, the Nile. The original, these little pygmies, followed by the Masābe negro, the Nilotic negro, and an evolution gradually taking place from this centre and various migrations going out to inhabit the world, each exodus carrying with them all that had been learnt up to that time,—when this is understood then the history of the past will become an open book. I have not retraversed Dr. Smith's able article and my own in the *Standard*, as these can be referred to by any of your readers who may feel interested in the subject, one which requires a large volume to set forth all one knows and which I hope to publish soon, as it is nearly completed.

I am, Sirs, yours faithfully,
ALBERT CHURCHWARD, M D. Brux., M.R.C.P. Edin., M.R.C.S. Eng.

Sept. 2nd, 1905.

PS.—In line 2 of the hieroglyph paragraph commencing "to dance" "is *Āx* or *za*" should read "is *āxa* or *āza*."

IRRATIONAL TREATMENT OF THE SEVERELY INJURED.

To the Editors of THE LANCET.

SIRS,—It is almost an every-day occurrence to find in the daily press a record of some mishap in which the victim is severely crushed or mangled. The account describes how a medical man was fetched who ordered immediate removal of the patient to the hospital. At the inquest the house surgeon reports that the patient was admitted in a state of collapse, from which he never rallied, and died a few hours later. In these cases the post-mortem examination frequently demonstrates injuries which are not incompatible with survival of the patient. The error of moving a man in a state of collapse a long distance is as frequent as it is inexcusable. If a patient is in a state of collapse the most certain method of diminishing or obliterating any chance he may have of recovery is to move him, often in a jolting, uncovered conveyance, a long distance. His destination, it is true, may be the hospital but that does not alter the fact that a patient, already nearly dead, has had his condition aggravated and his chances of recovery minimised by being unnecessarily moved about.

While it is inadvisable to leave a severely injured man in a gutter or open field, his removal to the nearest place of shelter, usually a distance of only a few yards, is all that is necessary or justifiable. Here, under the influence of stimulants and warmth, he will recover from the shock, if such recovery is compatible with his injuries, and later may, if necessary, be removed to hospital. With the possible exception of cases of internal hæmorrhage or injury to internal organs, conditions which are frequently combined or indistinguishable, the immediate treatment of a severely injured patient can nearly always be summarised, as arrest of hæmorrhage, rest at or near the scene of the accident, warmth, stimulants, and saline solution injected either into the rectum or into a vein or into the subcutaneous tissues, and if pain should be a marked feature hypodermic injection of morphine. A variation of the newspaper account of the inquest is as follows. "The house surgeon stated that the deceased was admitted in a state of collapse, the crushed limbs were at once amputated, but the patient never rallied and died the same evening."

Very few severely injured patients survive the extra shock produced by immediate removal to hospital followed at once by an operation under an anæsthetic. This raises the question of the treatment of accident cases brought while in a state of collapse to a hospital. The fact of a limb being crushed beyond hope of recovery does not justify its immediate removal. The retention for some hours or even a day of a mangled limb will not kill the patient but its removal plus the administration of an anæsthetic while the patient is in a state of collapse is apt to be the proverbial last straw. The immediate treatment of a patient who is brought collapsed to a hospital should, as a rule, be limited to combating the collapse, immediate operation being reserved for cases such as those with internal hæmorrhage which is still active, in which immediate operation is really essential. The removal of mangled portions of a patient who is in a state of collapse may be operative but cannot by the wildest stretch of imagination be justly described as surgical.

I am, Sirs, yours faithfully,
C. HAMILTON WHITEFORD.

Plymouth, August 29th, 1905.

THE TECHNIQUE OF THE EXAMINATION OF SPUTUM FOR TUBERCLE BACILLI.

To the Editors of THE LANCET.

SIRS,—I quite agree with Mr. C. G. Higginson in his article upon the subject of the examination of sputum. In all cases where there is expectoration such an examination ought to be as much a part of the routine examination of the case as auscultation or percussion. We are all fallible, but I am sure from cases which have come under my notice that some mistakes which have entailed the most terrible distress might have been avoided if the sputum had been examined. Looking back on my own experience I can quite understand that the objection to this necessary examination, which ought to be undertaken in all such cases before one can make a diagnosis or dare to attempt a prognosis, is that it takes too much time to make and that it is not always convenient to send the sputum to be examined besides costing money. Encouraged by Mr. Higginson's words I venture to describe a technique begun in the Pathological Laboratory at Heidelberg under my revered master the late Professor Arnold and perfected by practice and the helpful hints of other workers. I do so because to many some parts of it may be new, and one very minor detail I believe to be my very own! It has also the advantage of quickness, seeing that by following the routine carefully I can complete the whole investigation, from taking the lid off the sputum pot to seeing the bacilli under the microscope, within ten minutes. Therefore when a patient comes to me coughing and he can give me a piece of phlegm, as patients generally can, I make the examination whilst he (or she) is slowly putting on his clothes and resting a few minutes after the exertion. The presence of the bacilli enables one to speak definitely, whilst their absence merely makes one ask for the first piece of phlegm brought up in the morning, according to the usual rule. That, however, occurs much less often than one would think; more seldom even does one have to reverse the verdict through the discovery of bacilli in the second or even third specimen of phlegm.

In one of my consulting-room windows stands a small table on which are the various instruments and materials for the examination of sputa, blood, and urine. For the examination of the sputum for tubercle bacilli I have: 1. A small microscope with a Zeiss six-millimetre apochromatic objective and a × 10 eyepiece, or a Watson one sixth of an inch holostigmat objective with the same eyepiece, or a Swift one-eighth of an inch objective with a No. 3 eyepiece. An oil immersion lens takes too much time and is quite unnecessary. 2. Clean glass slips. I use Scrubb's cloudy ammonia to clean them; much depends on this. 3. Thin cover-glasses that have been cleaned by dropping into strong nitric or sulphuric acid, washed in running water and stored in strong alcohol smelling of ammonia. 4. Spirit lamp. 5. Forceps. 6. Scissors. 7. Silk handkerchief and piece of soft chamois leather. 8. Carbol-fuchsin solution kept in a bottle with rubber cork, in which a small glass filter is fitted kept supplied with filter paper. 9. Löffler's blue in a drop-bottle. 10. Vaseline in a bottle with a rubber cork, with a glass rod thrust through it. 11. Bottle with cedar-oil or Canada balsam dissolved in xylol. 12 Beaker containing clean water. 13. Beaker containing 20 per cent. solution of sulphuric acid. 14. Beaker of clean water. 15. Matches. With these, each in its own place, on the table and the sputum (if in a bottle or freshly coughed up) in a black vulcanite dish such as photographers use for a quarter-plate developing dish before one: 1. Light the spirit lamp and keep the match used. 2. Pick out an opaque piece of sputum with the forceps and sever it from the mass with the scissors. The black dish shows up small opaque spots in the mass of muco-pus and thus saves useless labour in making films in which no bacilli are likely to be present. This point is very necessary to success. 3. Place this in the middle of one glass slip and pressing the surface of the distal third of another slip carefully upon it so as to flatten it well out slowly slide the upper slip off the lower, keeping the surfaces carefully in contact. When this is properly done and if the slips are clean a beautifully thin film will be left across the centre third of the lower slide. As in making blood films this is of great importance and must be learned. 4. Lean the slide up to dry whilst you are (*a*) placing the other slip in a bowl of disinfectant that always stands handy; (*b*) holding the forceps in the flame whilst you count ten slowly; and (*c*) doing ditto with the scissors, afterwards wiping them clean with soft paper that is duly burnt. Should the film not be quite dry (it depends on the state of the atmosphere once you have learned to make a film properly without little excrescences) hold the slide, film side uppermost, six inches above the flame and wave slowly backwards and forwards until the film is dry. 5. Hold the slide, film uppermost, in the flame whilst you count ten slowly. 6. An eighth of an inch from the film on either side of it draw a line with the glass rod dipped in vaseline. This leaves a ridge of vaseline on either side of the film and forms a dam when (7) some carbol-fuchsin solution is dropped through the filter fitted with filter paper. Put on plenty as the vaseline ridges will prevent it running all over the glass slip on to your fingers (it then frightens the patients) and your clothes (it then annoys you). 8. Hold the slide six inches above the flame until the vaseline melts and the stain smokes. The vaseline acts as an indicator and prevents the solution being overheated, which I have proved is bad for staining purposes. 9. Lay the slide thus heated down on the table for four minutes by the watch. Two minutes I have found quite sufficient but let it have four. While waiting take the cover-glass out of the alcohol and polish it with a handkerchief or leather. Lean it up in a fixed spot, for it is sometimes hard to find cover-glasses when their location is changed every time and there is no time to look for it. 10. The four minutes being up dip the slide into the beaker of water, waving it backwards and forwards three times. 11. Dip it into the sulphuric acid solution, doing the same, then back into the water. Now if points of bright colour appear dip it again into the sulphuric acid. In fact, the film must go backwards and forwards between the two beakers until the film has a uniform greyish-pinkish colour. Experience has shown me that there is little danger of decolourising the bacilli with 20 per cent. solution of sulphuric acid unless the slide be kept continuously in that solution over eight minutes, whilst our process ought not to take one minute. 12. Drop Löffler's blue on the film until it is quite covered, then without delay dip the slide into the last beaker of water. I find that half a second is enough to stain and longer makes the blue staining too pronounced. After waving the slide in the water backwards and forwards three times take it out and with the handkerchief wipe the slide dry, removing the vaseline at the same time. 13. Dry off the water with fluffless blotting paper and wave the slide to and fro six inches above the flame. It quickly dries. 14. Drop a tiny drop of cedar oil in the centre of the dry film, lay down the cover-glass upon it, and press gently with the butt end of the match used for lighting the spirit lamp. 15. Place on the stage of the microscope, which you have put in readiness before you whilst the film is finally drying (see 13), focus with the eye to the eyepiece (the proper way and should be learned), and before the tenth minute expires you ought to see (if they be there) dark red rods on a pale blue ground.

The book I always keep handy is Dr. W. d'E. Emery's "Bacteriological Diagnosis." The staining solutions are made from Burroughs and Wellcome's tabloids for the purpose, but the only "Gram" I have been really successful with is Martindale's; from him also I got the bottle with the filter in the cork and vaseline bottle—really for hanging-drop work. I mention these things as so much depends upon the stains and Dr. Emery makes the pursuit a fascinating one. Some may think a Zeiss apochromatic six millimetres with × 10 eyepiece much too weak. I tested the matter by showing my little girl of 11 years a film prepared as above with that magnifying power and she described the little rods on a blue ground exactly the first time.

I am, Sirs, yours faithfully,

D. ANDERSON-BERRY, M.D. Edin., F.R S. Edin.

St. Leonards-on-Sea, Sept. 1st, 1905.

To the Editors of THE LANCET.

SIRS,—I have read with interest the article by Mr. Higginson on the examination of sputum in THE LANCET of August 26th (p. 600), together with your note on the same and should like to make one or two comments thereon. I find that a very thin film of sputum is of less service than a moderately thick one, especially in those cases where the number of tubercle bacilli is small, as there is more chance of finding them in a thicker layer than in a thin one.

I prepare my films by squeezing a small piece of sputum between two slides as they are more easily handled and less easily broken than cover-slips. Then as regards reagents, I keep them all, except carbol-fuchsin, in short, wide-mouth bottles, so that the slide can be dipped into the solution without troubling to pour any out. This plan was used by the late Dr. A. A. Kanthack and is, I think, cleaner and less wasteful than any other. Where a tap is not available water can be employed in the same manner and frequently changed. I think that the carbol-fuchsin solution wants frequent filtering. I quite agree that decolourising and counter-staining simultaneously is a mistake.

On the whole Mr. Higginson's article should prove of value, because it gives exact details of a process which, though apparently simple, is often a failure from want of knowledge of detail.

I am, Sirs, yours faithfully,

GEORGE A. CRACE-CALVERT.

Vale of Clwyd Sanatorium, Ruthin, North Wales, August 30th, 1905.

PYELONEPHRITIS IN PREGNANCY.

To the Editors of THE LANCET.

SIRS,—I was much interested by the annotation which appeared in THE LANCET of August 26th on the subject of pyelonephritis in pregnancy, my attention being particularly drawn to it by the occurrence of one such case in my practice. The patient, aged 34 years, a primipara, from whom a vesicular mole had been removed one year previously, was delivered by forceps on August 1st of a living child after a somewhat difficult labour owing to pelvic contraction. I sutured a complete tear of the perineum which various circumstances had rendered unavoidable and during the next four days retention necessitated the regular use of the catheter. In spite of strict aseptic precautions a mild cystitis, characterised by hypogastric pain and tenderness and by stale, turbid, faintly acid urine, was noticed. There was no rise in temperature or acceleration of pulse, which both remained normal throughout, and the symptoms promptly yielded to salol, alkalies, and hyoscyamus. On August 24th, four days after the patient had been allowed up, she complained of headache, giddiness, great muscular weakness, and refused food. (Her appetite had hitherto been excellent.) When I saw her she looked weak and tremulous, the face was puffy, and the skin was harsh and dry. The temperature was 102·4° F.; there was severe pain in the left loin radiating down to the hypogastrium, also tenderness on deep palpation. There was no history of shivering. Micturition was frequent; the urine was dark, scanty, acid in reaction, and contained a large trace of albumin. The patient was ordered back to bed, placed on a milk diet, and salol and alkalies were administered. The pain and tenderness soon diminished. The temperature gradually came down, the evening record becoming normal five days later. At the same time the urine increased in quantity, the amount of albumin present was markedly less, and a careful examination failed to reveal casts or epithelial cells which had been found at the onset.

The renal symptoms noticed on August 24th can scarcely have been due to an ascending infection from the lower urinary apparatus, since the very mild cystitis had cleared up by the eighth day. Moreover, I believe cystitis to be not infrequently connected with wounds of the rectal mucous membrane. Neither can the events be attributed to sepsis, since the rent healed practically by first intention and no untoward symptoms were manifested during the whole course of the case till August 24th. Was the (!) pyelonephritis possibly due to an infection by bacillus coli invading a ureter injured by pressure?

I am, Sirs, yours faithfully,
V. A. CHATELAIN.
Goodmayes, Essex, Sept. 2nd, 1905.

A MOTILE ELEMENT RESEMBLING AMŒBA PROTEUS IN THE PRIMARY AND SECONDARY LESIONS OF SYPHILIS.

To the Editors of THE LANCET.

SIRS,—In order to see this element in an active state it is essential that the patient shall not have taken mercury, otherwise the motility, the most distinctive feature of the element, will be inhibited. The observations were made on excised primary chancres and secondary papules.

The chancres and papules are placed immediately after excision (under a general anæsthetic) in sterile normal saline solution. After two hours in this solution scrapings are made with the edge of a sharp knife from the deeper portions of the chancre, the more superficial surface epithelium being first removed and rejected. The deeper or cut surface of the papule is similarly scraped and the scrapings are suspended in a drop of sterile normal saline solution tinted with neutral red. The hanging drop preparation is examined on a cold stage. Small naked masses of protoplasm varying in size, unstained, of a greenish hue, with finely granular contents and without apparent nucleus, will be seen. On watching these, very active movements, such as the putting out of pseudopodia, rapid general alteration in contour and streaming of the protoplasm, will be readily observed. From two to five hours after excision of the syphilitic lesions all movement ceases and cannot be restarted by means of raising the temperature of these elements to 37° C. This is a preliminary communication.

We are, Sirs, yours faithfully,
T. P. BEDDOES, F.R.C.S. Eng.

THE HONOUR OF THE MEDICAL PROFESSION.

To the Editors of THE LANCET.

SIRS,—Some time ago my attention was directed to the prospectus of the Bucci Medicine Syndicate, in which I was described as chairman-director. As the use of my name was entirely unauthorised and I had had no previous knowledge of the prospectus and had never had the remotest connexion with the concern I immediately instructed my solicitor, Mr. Sidney Newman, to deal with the question, with the result that two abject apologies were at once tendered by the proprietors of the business and an assurance proffered that the prospectus had been circulated privately only and to a most limited degree and that it had been forthwith entirely withdrawn. Endless inquiries failed to disprove these statements and to this date I have never heard of nor come across a copy of the document referred to except the single copy supplied by my informant.

Though my full identity is given on the circular, I have never in any form received any communication in this connexion. Neither comment nor complaint nor inquiry either from friends or critics has reached me and there is no evidence so far to lead me to suppose that this document has either deceived or injured any member of the public or medical profession, myself excepted. In these circumstances I considered it beneath my dignity to notice the matter in the press and I further felt that the issue of a "disclaimer" on my part, on a matter which the public would readily value at its true worth, might be regarded as superfluous and possibly as a disingenuous attempt to spread my name. I had assumed, I think not unnaturally, that my own honour was in my own keeping and that the medical profession would be safeguarded by the various agencies supported for their protection. The British Medical Association, however, has recently given the subject their attention and expressed the opinion that in the interests both of the medical profession and myself the case constituted a cause for a public disclaimer on my part, though they do not appear themselves to have taken any steps in the matter. Accordingly, with the sanction of this recommendation, I willingly put on record my repudiation of this syndicate both on behalf of the medical profession and myself and beg to ask the indulgence of due publicity.

May I be permitted to add that in the light of the explanations I have offered I do not feel that any apology is due from me for the reticent policy I have adopted.

I am, Sirs, yours faithfully,
DENNIS VINRACE.
South Kensington, S.W., August 24th, 1905.

INEBRIETY A DISEASE AND THEREFORE TO BE TREATED BY THE MEDICAL PROFESSION.

To the Editors of THE LANCET.

SIRS,—I have read with interest Mr. W. McAdam Eccles's letter in THE LANCET of August 26th, p. 628, and hail with delight the hope which he holds forth that for the future inebriety will be treated as a disease by those capable of dealing with it. I do not think that blame for the old and bad method of dealing with drunkards has been entirely due to the "clerical satellites" of quacks, as Mr. Eccles seems to suggest. As a member of the clerical profession I for one have felt for years past that we were dealing with a very serious problem in a very flippant and ineffective manner; I do not believe, I repeat, that the clergy should bear the whole brunt of the blame. Medical men themselves have held aloof from a preventive and curative work in which they should have been foremost, and I feel convinced that if any real advance is to be made in curing patients suffering from the disease of intemperance it will be made only on scientific lines by persons scientifically trained.

I am, Sirs, yours faithfully,
RICHARD FREE.
St. Cuthbert's Lodge, Millwall, E., August 31st, 1905.

ACIDURIA AND DEATH FOLLOWING THE ADMINISTRATION OF AN ANÆSTHETIC.

To the Editors of THE LANCET.

SIRS,—The two main facts noted in death following the administration of an anæsthetic appear to be the presence of a fatty liver and acetone in the urine. The question appears to have arisen whether the fat in the liver precedes or follows the administration of the anæsthetic. Dr. Leonard G. Guthrie considers that it precedes the administration and my pathological experience would lead me to believe that his view is the more likely to be correct. A liver considerably enlarged owing to the presence of fat is not uncommonly seen in children after death and is most frequently associated with some condition of sepsis. In such cases the amount of fat present may be very great, though it may be remarked that it is by no means in every case of septicæmia that there is a distinctly fatty liver, nor is it necessarily in the most intense septicæmia that there will be the most fat. It may be interesting to mention that only recently I made a post-mortem examination where it seemed to me that a typical example of a fatty liver occurring in a child was secondary to septic absorption from an abscess in the neck. Not until some hours after having completed the examination did I learn that 24 hours before death the child had been given an anæsthetic. Although I believe that a great excess of fat may appear in the liver very rapidly, it seems to me to be highly improbable that this liver, which extended three inches below the costal margin, had attained its abnormal size in the 24 hours of life which followed the administration of an anæsthetic.

The second point of interest that has been noticed in these cases of delayed death after an anæsthetic is the presence of acetone in the urine, and associated with this condition of the urine one of the most striking symptoms is vomiting. Acetonuria is, it is needless to say, a marked feature of the cases known as "recurrent vomiting" in children. Severe cases of this affection are not very often met with, but milder examples, which Dr. Guthrie speaks of under the popular name of "bilious attacks," are common. It does not seem to me, however, that a fatty liver is necessarily associated with acetonuria and recurrent vomiting in children. Fatal instances of this affection are rare but it has fallen to my lot to perform the necropsy on a case where death occurred. The urine contained acetone but although I did not examine the liver microscopically it was certainly not what could be called a fatty liver. It was not in any degree enlarged and presented no abnormal appearances to the naked eye. But even if it be allowed that microscopical examination may have shown in this case some excess of fat in the liver it seems to me to be difficult to believe that fat in the liver can have anything to do with a disease which lasts for years, as does recurrent vomiting. Not only does it seem to me to be very doubtful whether a fatty liver can play a part in the causation of acetonuria associated with recurrent vomiting, but the question arises whether it is an important factor in the causation of acetonuria, vomiting, and death after the administration of an anæsthetic. That a well-marked fatty liver may be present it is impossible to deny. I have already mentioned a case that has come under my own notice but before great stress is laid upon the presence of a fatty liver one must be sure that in virtually every fatal case the amount of fat in the liver is really definitely above what is commonly present.

I am, Sirs, yours faithfully,

Sept. 3rd, 1905. THEODORE FISHER.

THE SPA TREATMENT OF CIRCULATORY DISORDERS.

To the Editors of THE LANCET.

SIRS,—In his paper on the Spa Treatment of Circulatory Disorders in THE LANCET of August 5th, Dr. L. Williams gives many valuable hints as to the pathology and treatment of these affections but bases his verdict on Nauheim in special on wrong views regarding its climate, the physiological action of its springs, and the methods of treatment used there. I hope to conduce to a correct understanding of the facts by the following statements.

1. *Climate.*—From the end of May till the end of June and September again are the finest times of the season, which lasts from May 1st to Oct. 1st. During these months the temperature is equable, neither excessively hot nor disagreeably cool. September, more especially, is by no means rainy, as Dr. Williams believes, but, on the contrary, is noted for the constancy of fine weather which, in conjunction with the bracing qualities of the air peculiar in these latitudes at the end of summer and beginning of autumn, perhaps renders this month climatically the most invigorating one of the whole year. July and August have hot days here as everywhere in these latitudes but the proximity of the Taunus hills and the prevalence of easterly winds render the nights agreeably cool even then, and rarely does a spell of hot weather last more than a few days without being relieved by a change of weather; these "sudden and decided changes" are a distinct advantage then at this time of the year, whilst at others they are no more pronounced than anywhere else.

2. *Physiological action.*—The theory that the carbonic acid brine baths chiefly act by stimulating the heart to more energetic contractions and increasing blood pressure is antiquated and has been replaced by the theory that the action is chiefly due to lessening of peripheral resistances in the vessels. The fact is that in high blood pressure this is generally lowered by the baths, whilst only cases of abnormally low pressure and loss of arterial tension experience an increase of blood pressure and of vascular tension through the baths. To explain this monistically I have advanced the following theory: As is known, the action of the baths is twofold—(1) local, consisting in dilatation of the capillaries of the skin; this means decrease of peripheral resistance; (2) reflex by stimulation of the cutaneous sensory nerves, the stimulus acting on the centres of the vaso-motor and pneumogastric nerves; this brings about increase of arterial tension with consequent rise of blood pressure and slowing of the heart's action (stimulation of the vagus). In cardiac disorders, however, the diminished velocity of the current of the blood leads to an accumulation of carbonic acid gas in the blood; this, we know from physiology, stimulates the vaso-motor centres in the medulla and brings about arterio-spasm; hence in so many cardiac cases we meet with an excessively high blood pressure. Further, we know from physiology that the velocity of the circulation is the greater in a given section of the vascular system the greater the propulsive power at the beginning of the said section, and the less the resistance at its end be; the capillary dilatation reduces this resistance, thus accelerating the circulation. The acceleration leads to the elimination of the accumulated carbonic acid; this being eliminated the abnormal stimulus on the vaso-motor centre is abolished and consequently blood pressure falls in these cases. The stimulating action of the baths on the vaso-motor system therefore only comes into action so far as to increase an abnormally low tonus towards normal, but not beyond this. And practically this theory is corroborated by our seeing good results from the Nauheim baths in cases of high blood pressure as well as in cases of low blood pressure. The chief effect is to relieve the heart (1) by capillary dilatation in all cases; and (2) by removing arterial spasm in cases where it exists. There is no physiological basis for assuming that the heart is stimulated itself actively to more vigorous contractions. Even the re-establishment of lost arterial tone would not act as a stimulus but as a relief to the heart, because in normal tone the elasticity of the arterial walls constitutes an important driving power and thus the vessels resume their share in propelling the blood which during the stage of lost tension had devolved upon the heart. Only the temperature, therefore, in cool baths throws an initial strain upon the heart and stimulates it to stronger contractions by bringing about contraction of the cutaneous capillaries; but this we entirely command by regulating the temperature at will. Stimulation of the vagus reduces frequency *and force* of the systoles; that of the accelerans cordis increases both. Both centres can be stimulated through reflex from sensitive nerves; but if both be stimulated simultaneously the action of the *vagus prevails.* Digitalis causes slower *and stronger* beats; this latter, therefore can only be due to direct action on the *intra*-cardiac centres, which is all the more probable, as we know that these are the predominating factors in regulating the heart's action. Such action on the cardiac muscle, however, can only be possible either by a chemical substance contained in the blood (as is the case with digitalis) or *perhaps* by electrical stimulation, but not by a stimulus only applied to the surface of the body.

3. "THE *Nauheim method.*"—Baths and exercises, it is true, were originally the only method known at Nauheim of treating cardiac disease. But "tempora mutantur nos et mutamur in illis." There are upwards of 50 physicians now practising at Nauheim, and it would not seem quite illogical to conclude that some of them had the capacity of treating patients on their own lines and of evolving original methods other than those exclusively in vogue formerly. The action of hydro-electrical baths on the circulation was established beyond all doubt as far back as 1883 by Eulenburg by *exact* research and since then by others. I may say that my own recent investigations have led, in conjunction with the light thrown on the subject by former work, preliminarily at least, to an exact definition of the action of baths with the faradic or sinusoïdal alternating current on the circulation. Without any doubt they have the following influences: (1) stimulation of the cutaneous sensory nerves with effect on arterial tone; (2) acceleration of the circulation by rhythmic contractions of the systemic muscles; (3) potent effects on metabolism; and (4) a beneficial effect on the general nervous system. Besides these, the baths have *possibly* a direct action on the vessels and the heart, as they undoubtedly have on other internal organs (intestines, uterus, and bladder).

It would go beyond the scope of a letter to adduce all the physiological facts and practical experiences which help to show that a combination of hydro-electrical methods with the Nauheim baths is *the best* physical treatment for circulatory disorders at the present day. but as this combination took its origin at Nauheim I protest against the "baths and exercises" henceforth being called *the* Nauheim method unless some qualifying words be added. With regard to the exercises, I am, with Professor A. Hoffmann, of opinion that in combination with the baths they are generally contra-indicated.

A word about the Nauheim treatment at other places. There is, of course, no doubt about the possibility of it, but the fact that many different spas on the continent, as well as in England, are making energetic endeavours to gain a reputation in these methods goes to prove the efficacy of them if *judiciously* applied. It should not be forgotten that the different qualities of the Nauheim waters and the balneological technique are necessary to insure the effects. Physical treatment of cardiac disease, whether by mineral baths, by exercises, or by hydro-electrotherapy, or by any combination of these, is, I quite agree with Dr. Williams, not followed by miraculous results, and is in general only indicated in initial stages.

I am, Sirs, yours faithfully,
PAUL C. FRANZE, M.D.

The Electrological and Radiological Institute, Bad Nauheim
(Germany), August 29th, 1905.

RHEUMATISM AND CLIMATE: A QUERY.

To the Editors of THE LANCET.

SIRS,—I shall be grateful if any of your readers will kindly help me with advice. I have been engaged in wide and wild country practice for the last 14 years and have lately suffered more or less from rheumatism and have also been laid up with lumbago and sciatica. The least wetting or even a long tiring day causes slight recurrence of the trouble. I am at present in a damp climate with clay subsoil in the North of England and am afraid I shall have to make a change. For various reasons I require a bracing place and am fond of seaside or health resort practice. I am middle aged. I shall be very glad of suggestions as to the most suitable districts in which to look for a practice where I may have reasonable hope of escaping an insidious foe and at the same time making a living.

I am, Sirs, yours faithfully,
August 29th, 1905. PRACTITIONER.

THE METROPOLITAN ASYLUMS BOARD AND ITS ASSISTANT MEDICAL OFFICERS.

To the Editors of THE LANCET.

SIRS,—We thank Mr. Scovell for his prompt reply to our letter which appeared in THE LANCET of August 26th and are pleased to note that he considered the question one of sufficient importance to occupy the early attention of the Board. From the opinions which he has expressed we are forced to believe that the Board can neither be fully acquainted with the position of its medical officers nor with the working of the rules by which its institutions are governed. We trust that a thorough inquiry will place these matters in a true light, and until such inquiry has been made the object of our resigning will not have been attained and the position of the assistant medical officers under the Metropolitan Asylums Board will continue to be an extremely unsatisfactory one.

We are, Sirs, yours faithfully,
FRANCIS R. BARWELL.
GERARD A. HERKLOTS.
H. P. KENNARD.

Darenth Asylum, Dartford, Kent,
Sept. 5th, 1905.

NEW HOSPITAL FOR THE ROYAL CORNWALL SAILORS' HOME AT FALMOUTH.—A few years ago Sir Joseph Fayrer and other members of the medical profession urged on the subscribers of the Royal Cornwall Sailors' Home at Falmouth the necessity of providing a new hospital for that institution. The old building has been in existence about 50 years and it was quite impossible to bring it up to modern requirements. It was consequently decided to erect a new hospital and subscriptions were invited for that purpose. On August 24th Vice-Admiral Sir Lewis Beaumont, commanding Plymouth naval station, laid the foundation stone of the new building in the presence of a large assembly. The hospital will stand in a large garden and will consist of a men's ward for six beds, with two small wards for one bed and two beds respectively. The building will also contain an operating theatre, convalescent ward, nurses' rooms, and the usual offices. The estimated cost is £2500, of which about £1300 are still required.

THE SALE OR PURCHASE OF A MEDICAL PRACTICE.

(FROM A LEGAL CONTRIBUTOR.)

ALTHOUGH in the majority of instances the sale or purchase of a medical practice is a plain and straightforward transaction, cases sometimes occur which tend to put the young practitioner who is unfamiliar with the ways of the world upon his guard. Moreover, even in cases where everything is fair and above board, one who is unaccustomed to the perusal of legal documents may set his hand to some deed of which he does not understand the true meaning. In these circumstances it is apprehended that our readers may value a few notes upon the subject of agreements for the sale and purchase of a medical practice.

Advantages of an agreement in writing.—If a practice is to be sold the terms of the sale should be reduced into writing and the agreement executed with the least possible delay. In the case of May *v.* Thomson ((1882) 20 Ch. D. 705), the plaintiff, who wished to sell a medical practice with the lease of the house where it was carried on, placed it on the books of a medical agent. This led to negotiations with the defendant. The premiums asked for the practice and for the lease were stated in a letter from the agent to the defendant, but no time for completing the purchase was mentioned. The defendant replied in a letter to the agent accepting the terms offered and adding that he should be ready to pay the deposit money "on receipt of corrected agreement," and at the same time he wrote to the plaintiff personally, also accepting the terms offered and adding—"I shall trust you to give me the best introduction you can during three months and afterwards if necessary." The plaintiff replied thanking the defendant for acceding to his terms and saying that "it would be his aim as well as his duty to give him an effectual introduction to his patients." A formal agreement was drawn up and never signed, and after some further correspondence the defendant refused to complete the purchase. Upon an action being brought by the vendor to obtain an order for specific performance, the Court of Appeal held that inasmuch as the time for the commencement of the purchase was left uncertain and the stipulation as to three months' introduction was not agreed to, and as the parties contemplated a formal agreement, there was no binding contract between the parties and the action was dismissed.

Perhaps the most satisfactory method of explaining the incidents of a regular transfer of a medical practice is to set out the clauses of a form of agreement which may be signed by the vendor and purchaser, adding such explanatory notes as appear to be necessary. Certain observations of a general nature may first be made.

Ascertainment of the price.—The all-important question, What price is to be paid? must first be satisfactorily determined. The vendor will naturally seek to enhance the value of the practice while the purchaser will seek to decry it, and the basis of agreement will probably be the books which have been kept by the vendor. Both vendor and purchaser should exercise the utmost caution in the use of these books; the vendor because if it should transpire that the books are in any way misleading, or that there has been any *suppressio veri* in connexion with them, unpleasant consequences may follow, and the purchaser because books of account though honestly and accurately kept may nevertheless mislead a person who does not properly understand them.

Let us take for the sake of illustration an extreme case. Suppose the vendor were to produce books which showed gross receipts of £1000 a year for two or three years and the purchaser, relying upon the books, gave a sum of £2000 for the practice and afterwards discovered that the books had been "faked" for the purpose of enhancing the apparent value of the practice. In such a case the whole transaction might be set aside on the ground of fraud. Where, however, the books are honestly kept and the purchaser has been content to rely upon the figures contained in them in arriving at the conclusion that a fair price has been asked, he cannot be heard to complain if he is disappointed with the takings of the practice. For instance, supposing a large part of the takings which were entered in the books were derived from two or three wealthy patients. Suppose these patients had left the district before the sale of the transfer. It is an open question whether the vendor should have disclosed this fact; a right-minded vendor would assuredly do so. Nevertheless the careful purchaser ought to make inquiry with regard to them, for it must not be forgotten that the maxim *caveat emptor* applies to the sale of a practice just as it applies to the sale of wares and merchandise. We have mentioned one pitfall for the unwary; there are many others which may escape the notice of a man who is unaccustomed to books of account. The best advice that can be given is to recommend a would-be purchaser to employ an accountant who is skilled in such matters to audit the books.

Dealings with agents.—The vendor of a practice will usually employ an agent to procure him a purchaser upon the terms that the agent shall have a commission on the purchase price. A few observations as to the rights of an agent may here be made. Commission is payable when the transaction in respect of which it is claimed is a direct though not necessarily an immediate result of the agency (Bowstead's "Law of Principal and Agent," p. 177). So if a practitioner employs an agent to sell his practice, and before the agent introduces a purchaser the practitioner sells the practice by private treaty with a friend, the agent cannot have a commission. But an agent is entitled to his commission if he indirectly introduce a purchaser, as where, for instance, the purchaser gets to know of the practice being for sale through seeing an advertisement inserted in a newspaper by the agent. The agent is also entitled to commission if he introduces a purchaser and the purchaser subsequently goes off through no fault on the part of the agent. So if a practitioner decides to sell his practice and an agent introduces a purchaser who is willing to pay the vendor's price and the vendor then decides not to go further in the matter, in that case the agent is entitled to his commission.

Sale or lease of practitioner's house together with the practice.—In most cases where a practice changes hands the purchaser takes over the vendor's house either by way of purchase or by a lease for years. The fact that there is an agreement to buy or to take a lease is generally referred to in the agreement for the sale of the practice, but the conveyance or indenture of lease should be drawn up in a separate document to be executed at or about the time of the execution of the deed which transfers the practice. It is not proposed to consider the essential terms of a conveyance or lease in this article.

Agreement for the transfer of a practice.—The following are some of the more important clauses which (or variations of which) usually find their way into an agreement between the vendor and purchaser of a practice. Some of the clauses are taken from the Encyclopædia of Forms and Precedents (London: Butterworth and Co.) and others from "The Law of Medical Partnerships, &c." (1895), by Barnard and Stocker. In both of these publications complete forms will be found.

An agreement made the day of 1905. Between A B of No. 19, Raidfern Gardens, in the Borough of Kensington, in the County of London (hereinafter called the vendor), of the one part, and C. D. (hereinafter called the purchaser) of the other part. WHEREAS the vendor has for many years past carried on the profession or practice of a surgeon and apothecary at No 19, Raidfern Gardens aforesaid and is desirous of disposing of th[illegible] thereof And WHEREAS the purchaser is [illegible]ne at or for the price and upon the terms h[illegible] this Indenture witnesseth as follows.

If the purchaser is going to take over the house and surgery as well, either by way of purchase out-and-out or on lease from the vendor, mention is generally made of this fact in an additional recital.

1. *Vendor to make alterations:* The vendor shall within twelve calendar months from the sale hereof carry out and completely finish to the satisfaction of the purchaser the alterations specified in the schedule hereto to all that house and messuage known as No 19, Raidfern Gardens, in the Borough of Kensington, in the County of London, now occupied by the vendor, according to plans and specifications which have already been prepared and have been signed by the vendor and purchaser respectively. The vendor shall also before the day of put the said messuage and the outbuildings belonging thereto into thorough decorative repair to the satisfaction of the vendor.

The period of 12 months referred to in the foregoing paragraph is the period during which, by a covenant to which I shall presently refer, the vendor undertakes to give the purchaser an introduction to the practice. The repairing covenant above set out may be inserted in this agreement although the premises are sold or leased to the purchaser by a separate instrument.

2. *Sale of goodwill.*—The vendor shall sell and the purchaser shall buy the goodwill and interest of the vendor in the practice of a general medical practitioner heretofore carried on by the vendor at No. 1 Raidfern Gardens aforesaid and neighbourhood at the price of £ one half of which shall be paid on the day of and th balance thereof on the day of on which day the purchas shall be completed. [Provided always and it is hereby agreed an declared that nothing in these presents shall have effect to transfer t the purchaser any interest of the vendor in the appointment which h now holds as medical officer to the workhouse [or the friendly society], and provided further that nothing herein containe [illegible] in pursuance of an appointment] [illegible] clause).—In consideratio of the sum of £ as to £ [illegible] part thereof now paid to th vendor by the purchaser by way of deposit and part payment of th purchase money of the said practice (the receipt of which sum o £ the vendor doth hereby acknowledge) and as to £ th residue thereof to be secured and paid in the manner and at the time hereinafter mentioned, the vendor shall assign to the purchaser a from the day of [*here insert day of commencement of introduc tion*] all the goodwill and professional connexion of the vendor of an in the said practice now carried on by the vendor in and around No 19 Raidfern Gardens aforesaid and shall render to the purchaser as far a possible all the patients and customers of the said practice and th purchaser shall buy and acquire the same upon the terms herei mentioned.

Where there are appointments attached to the practice i is well that they should be specifically referred to in th agreement. The vendor cannot guarantee that the purchase shall receive such appointments if the purchaser resign them, and the vendor may desire to keep some of them in hi own hands. Any special arrangement with regard to the should be particularly mentioned in the agreement. With regard to the purchase money it is often more convenient to the purchaser to pay it by instalments. In that case the dates of each individual payment should be specially referred to in the agreement. The form which is now being discussed would only be suitable for the purposes of transferring a practice out and out; it would not be applicable to the taking in of a new partner. An arrangement of that kind would have to be embodied in a very different document.

3. *Assistance and introduction by the vendor.*—As from the date hereof the said practice shall be carried on by the purchaser for his own benefit but in and during a period of *twelve* months from the date hereof the vendor shall assist the purchaser in carrying on such practice [and shall use his best endeavours to secure for the purchaser the appointment of medical officer to the] and shall introduce the purchaser to all the vendor's patients and do all in his power to procure the full benefit of the said practice for the purchaser and to insure his success in carrying on and extending the same

3 (*a*). *Covenant to introduce purchaser*—The vendor shall continue to reside at No 19, Raidfern Gardens aforesaid from to , which period is called the period of introduction, and shall actively assist the purchaser in the conduct of the practice and so far as may be possible and consistent with professional etiquette shall introduce the purchaser to and endeavour to the utmost of the vendor's ability to secure for the purchaser the custom of all such persons as are or have been patients in connexion with the said practice and are still residing in or near No 19, Raidfern Gardens as aforesaid, and the vendor shall use his best endeavours to secure for the purchaser all the public and other medical appointments which the vendor now holds [with the exception hereinbefore mentioned] and which are, with the [illegible] estimated annual value of each such [illegible] schedule hereto, and the vendor shall b[illegible] from the work at the said practice and f[illegible] portion of the period of introduction not exceeding [illegible] days at any time and not exceeding weeks in the aggregate.

Inasmuch as the transfer of the goodwill takes place as from the date of the agreement, any debts due to the practice collected after that date shall belong to the purchaser. So much depends upon the introduction which the vendor gives that a clause is sometimes inserted for the protection of the purchaser if the vendor fails to give a proper introduction Sometimes a purchaser is given an option to terminate the time of introduction by some such clause as the following.—"Provided always that the purchaser shall have the option of terminating the period of introduction at any time on or after the day of on giving the vendor weeks notice in writing of his desire to terminate it."

4 *Remuneration for assistance*—As remuneration for such assistance the purchaser shall pay to the vendor half the net profits derived from the said practice (after deducting all outgoings and expenses in respect of work done) during the said period of twelve months

The term "outgoings" will include the rent of the house and taxes, the cost of purchasing drugs and instruments to be used in the practice, the wages of servants employed in the practice, and the cost of up-keep of horses, carriages, and motors.

5. *Deduction from purchase price if appointment not obtained.*—If the appointments referred to in paragraph 2 (*a*) or 3 hereof shall not be secured for the purchaser within the said period of twelve months the purchaser shall be at liberty to deduct from the balance of the said purchase money an amount equal to double the annual salary now paid in respect of such appointment.

If the purchase price has been calculated upon the basis that certain appointments shall go with the practice and it turns out that the vendor is unable to secure the reversion of these appointments to the purchaser it is only fair that the purchase price should be reduced.

6. *Restrictive covenant.*—The vendor shall not except as aforesaid practise as a physician, surgeon, accoucheur, or general practitioner (unless where he shall be *bona fide* called in to consultation by some other medical man) or as assistant to any medical practitioner within ten miles of No. 19, Raidfern Gardens [or attend any of his past or present patients] for ten years as from the date of these presents.

6 (a). *Restrictive covenant (another form).*—If the purchaser shall duly perform and observe the stipulations of these presents on his part to be performed and observed the vendor shall not at any time for the space of years after the commencement of the period of introduction, except as herein previously provided, exercise or carry on or be directly interested in exercising or carrying on upon his own account or in partnership with or as assistant to any other person the practice, profession, or business of physician, surgeon, accoucheur, or apothecary at any place within miles of No. 19, Raidfern Gardens, and if the vendor shall so practise within the limits aforesaid or in any way violate this provision he shall pay to the purchaser the sum [of £] [or of £ for every month or part of a month during which he shall violate this provision] as ascertained and liquidated damages and not by way of penalty.

The restrictive covenant is one of the most important in e agreement between the vendor and purchaser of a pracce. Without such a covenant being capable of enforcement would be idle for any man to buy a practice. It must, owever, be drawn with some care, for it involves a contract hich is in restraint of trade and is therefore contrary to aw, unless its terms are such as to be reasonably necessary or the protection of the purchaser without depriving the endor of his means of livelihood altogether. For instance, if medical practitioner were to enter into an agreement which revented him practising anywhere for the rest of his life, no ourt would compel him to carry out the agreement. So ong, however, as the covenant is limited either as to time or pace it will be enforced. For instance, a general practitioner in London could not interfere with a Liverpool practitioner, nor could an Irish practice compete with an English practice. It would, however, be reasonable in the case of a sale of a London practice to ask the vendor not to practise within ten miles of the house or within the county of London for a period of ten years. The following rule, which was laid down in the case of Horner *v.* Graves (7 Bing. 735), should be borne in mind: "The restraint must be only such as to afford a fair protection to the interests of the party in favour of whom it is given, and not so large as to interfere with the interests of the public."

The covenant, as expressed in our model clauses, is fairly wide, but questions do sometimes arise as to what constitutes "practising" within the proscribed limit. It would clearly be a breach of the bare covenant "not to practise" to enter into partnership with, or become assistant to, another practitioner. The latter point was decided in the case of Palmer *v.* Mallett ((1887) 36 Ch. D. 40). Assuming there is no proviso to the effect that *boná-fide* consulting practice shall be allowable it is difficult to say whether that class of practice would be regarded as a breach of the general covenant "not to practise." It is clearly safer to insert a special provision relating to consulting practice, for if it is not inserted and the purchaser desired to enforce his strict right it is apprehended that consulting practice might be prohibited. It will be noticed that in Clause 5 the words "or attend any of his past or present patients" are put in brackets. If these words are omitted there will be nothing to prevent the vendor seeing a former patient at some place outside the proscribed area.

7. *Collection of book debts.*—The purchaser shall be at liberty if he thinks fit to collect on behalf of the vendor all outstanding book debts in respect of the said practice up to the date hereof and the vendor shall not within calendar months from the date hereof commence legal or other proceedings for the recovery of any such debts.

Before the purchaser could sue a patient who owed money to the vendor it would be necessary for the vendor to give notice to the patient that he had assigned the debt in question. There need be no formality about this assignment.

8. *Discharge of book debts.*—The vendor shall pay and discharge all debts and liabilities in relation to the said practice subsisting on the day of , and the vendor shall pay and discharge all debts and liabilities which have accrued or been incurred since that date and mutual indemnities shall be given in respect thereof.

Suppose, for instance, the vendor had ordered certain drugs a month before the date of the agreement and the price of these drugs was still due and owing. The above clause would compel the vendor to pay the amount so due. In the absence of a clause in some such form as the above the purchaser might conceivably be held liable at the suit of the person who supplied the drugs.

9. *Books of account to be handed to the purchaser.*—The vendor shall hand over to the purchaser on the termination of period of introduction all the books of account relating to the said practice and such books shall become the property of the purchaser, but he shall permit the vendor, his solicitors, or agents to have access thereto at all reasonable times and to have the temporary use thereof at the purchaser's surgery or at any other place where the vendor may require the production of the same for the purpose of getting in the vendor's outstanding accounts.

10. *Drugs, &c.*—The purchase money hereinbefore mentioned shall include all such bottles, drugs, surgery fixtures, furnishing, and appliances (not being surgical instruments) as shall belong to the vendor and be used for the purposes of the said practice at the date last mentioned and shall not be expended during the period of introduction hereinafter mentioned.

11. *Execution of assignments.*—The vendor shall, if and when called upon by the purchaser, execute all proper assignments and other deeds for carrying this agreement into effect.

The assignments above referred to include the assignments of book debts which will enable a purchaser to sue for their recovery.

STAMPING OUT CONSUMPTION: WHAT THE POST OFFICE HAS DONE IN TEN YEARS.

(From a Correspondent.)

Should there be any doubt in the minds of workmen or their employers as to the possibility of stamping out the disease of consumption from any body of persons in whatever trade by adopting the methods recommended by modern science, that doubt ought to be for ever set at rest by a consideration of the following interesting little table compiled from the Postmaster-General's reports for the last ten years. Time was when the Post Office gave no space to the health of its employés in the annual blue book, but for the past ten years some five or six pages of tables and comments have been included. Contemporaneously with this, and indeed for some years prior to the commencement of this publication, there had been a deal of criticism, necessarily not supported by accurate figures, of the loss from a preventable disease, in such an easily controlled and specially selected community. This at length awakened the postal medical department to its duty in the matter and the figures compiled below will show with what excellent results.

The following table is compiled from figures extracted from the Postmaster General's Report for the year indicated and shows the loss from tuberculous disease among officers under the care of the official medical officer, as recorded in the reports for the years mentioned.

Year.	Staff.	Deaths	Retirements.	Total.	Loss per 1000 living.
1896 ...	62,362	86	67	153	2·4
1897 ...	76,966	72	80	152	1·9
1898 ...	79,121	70	87	157	1·9
1899 ...	82,172	62	83	145	1·8
1900 ...	84,305	53	90	143	1·6
1901 ...	87,242	61	93	154	1·7
1902 ...	91,402	53	119	172	1·8
1903 ...	96,862	52	82	134	1·3
1904 ...	100,762	60	119	179	1·7
1905 ...	118,541	73	123	196	1·7

The first thing that strikes us in glancing at this table is the remarkable decrease in the total loss, which represents, when taken over the 100,000 odd of the staff, a saving of a very large number of lives per annum. Perhaps, however, the cases of retirement do not now so certainly indicate imminent decease as they did ten years ago. For if we look again at the table we shall see a remarkable change in the relation between the number of retirements and the number of deaths. Whereas in 1896 the deaths exceeded by 19 the number of retirements, we notice that for all the remaining years the retirements exceed the deaths, the ratio of excess increasing as the years proceed. This is obviously the result of a deliberate policy to remove the infected persons from the service before death, and does indeed indicate that the employés tainted with consumption are now pensioned in the earlier stages. This policy has two excellent results: it gives the sufferer a better chance of the arrest of his disease and it removes a source of infection from the other employés. The ultimate and beneficent result is the diminution of the total loss as indicated in the final column.

But certain accessory agents have also been operating. First, there has been a good deal of educational literature circulated among the men and women which has resulted in a better appreciation of the value of fresh air, temperance, exercise, and absolute and minute cleanliness in all things. This was especially the case during and after the meeting of the great International Congress in London in 1901. In this year (October, 1901) the Postmaster-General issued, somewhat tardily it must be confessed, a prohibition against spitting. This was followed in 1903 by a lengthy instruction to all his administrative officers as to the proper methods of cleaning and ventilating the offices. Dry dusting was abolished and dry sweeping forbidden. A little later (1904) an exceedingly interesting circular setting forth the conditions of tuberculous infection, the means of prevention, and giving advice to sufferers how to act so that they should not be a danger to others, was printed on foolscap cards and hung in every office. All the new buildings now being erected and all the recently erected ones have been designed with a view to considering these things in the light of the modern knowledge of the disease. The net result has been a reduction of the total loss amounting in some years to nearly 50 per cent.

Such a result is exceedingly gratifying. It is satisfactory to those who first started the agitation for reform in 1895, it is satisfactory to the medical department that yielded to the representations, and it must be exceedingly satisfactory to the Postmaster-General himself. For, in addition to the good which accrues to his own department, he will have the satisfaction of feeling that his department has given a practical demonstration of the effectiveness of preventive measures that should do much to stimulate other large employers of labour and public bodies to do the same. It should also stimulate Lord Stanley to persist in the good work until pulmonary phthisis is as rare in the Post Office as small-pox. Eminent medical men have expressed the opinion that the disease can be practically eradicated from the Post Office. If so it should be done. The movement now afoot for the provision of a postal sanatorium should assist greatly in bringing about this desirable result.

HOMBURG.

THE PROBLEM OF MINERAL WATER HEALTH RESORTS.—WHAT SHOULD, AND WHAT DOES, DETERMINE THEIR POPULARITY.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

PART III.[1]

THE HOMBURG OF THE FUTURE: THE MEDICAL POSSIBILITIES.—THE NEW SPRING.—THE NEW BATHS AND METHODS.—DIET IN THE HOTELS.—EVER-INCREASING FACILITIES FOR THE TREATMENT OF PATIENTS.

Homburg, August, 1905.

As may be gathered from what has already been said, the future of Homburg depends on the manner in which its medical resources are appreciated and rendered available to an ever-increasing number of patients. These advantages have been multiplied notably of late years. The sanitation of the town, as already described, has now been brought up to a high standard of excellence. The efficacy and the usefulness of the waters in the treatment of disease were always admitted by those who were capable of forming an opinion on such a subject. But even in this respect there has been a recent startling and important improvement. Some years ago it was proposed to let a considerable part of the grounds in the park, which is between the Kurhaus and the mineral wells, to the golf club. The architect and antiquarian, Professor L. Jacobi, however, objected. He did not object to golf, but he insisted that the town should reserve the right to dig for water on the grounds, for there was historical evidence to show that the Romans had a valuable well on this site. Consequently a clause to this effect was introduced in the lease of the grounds to the golf club. A few years later the benefits derived from bathing in the mineral waters being more and more appreciated it became necessary to increase the supply of water. Thereupon it was decided to bore on the historical spot. Nothing was known as to the quality of the water likely to be obtained; it was only known that it had been used by the Romans for making salt. After digging to a considerable depth not only was mineral water obtained but it proved to be richer in its mineral constituents than any of the other wells in use. Whereas the most popular water—that of the Elisabeth spring—contains 11·032 grammes of salts in 1000 grammes of water, the new spring contained 14·269. The advantage of the new spring, which in reality is so old a spring that it had fallen into disuse, is that a smaller quantity of water will produce the same effect. Thus, for instance, roughly speaking, it will suffice to take two glasses of the Landgrafenbrunnen, the name given to the new spring, instead of three glasses of the Elisabethenbrunnen. There are consequently less gas absorbed, less distension, and less work for the heart. As it contains a larger quantity of magnesia as well as more salt it has a stronger aperient effect and may be used more advantageously in cases of obstinate constipation and for reducing fat. In this respect it can be placed side by side with the Marienbad waters. Then, as there are no sulphates, it is not so likely to produce depression. Other salt springs which very effectively reduce fat too often cause weakness. On the other hand, the Landgrafenbrunnen is not so easy to absorb and therefore when the patient has a delicate digestion he will have to fall back upon the Elisabethenbrunnen. Here, in any case, are the analyses of these two springs made by Professor Dr. H. Fresenius who is one of the greatest authorities in Germany:—

	In 1000 parts by weight of water.	
	Landgrafen-brunnen 1904.	Elisabethen brunnen 1901.
Sodium chloride (NaCl)	9·878044 ...	7·767251
Potassium ,, (KCl)	0·368389 ...	0·272864
Lithium ,, (LiCl)	0·020748 ...	0·015136
Ammonium chloride (NH_4Cl)	0·002594 ...	0·010648
Calcium ,, ($CaCl_2$)	1·760640 ...	1·281842
Sodium bromide (NaBr)	0·004135 ...	0·002954
Sodium iodide (NaI)	0·000018 ...	0·000032
Barium sulphate ($BaSO_4$)	0·001557 ...	0·001020
Strontium ,, ($SrSO_4$)	0·043435 ...	0·018033
Bicarbonate of strontium [$SrO(CO_2)_2$] ...	0·004741 ...	—
,, calcium [$CaO(CO_2)_2$] ...	0·974873 ...	0·802482
,, magnesium ([$MgO(CO_2)_2$]	1·108505 ...	0·780704
,, iron [$FeO(CO_2)_2$]	0·065196 ...	0·031527
,, manganese [$MnO(CO_2)_2$]	0·001738 ...	0·001753
Calcium arsenate [$Ca_3(AsO_4)_2$]	0·000130 ...	0·000199
,, phosphate [$Ca_3(PO_4)_2$]	0·000334 ...	0·000814
Silica (SiO_2)	0·034627 ...	0·025616
Total	14·269704 ...	11·032674
Free carbonic acid gas (CO_2)	1·834179 ...	2·300613
Total, including gas (CO_2) ...	16·103883 ...	13·333287

The local practitioners insist that the new spring can be compared with those of Carlsbad and Marienbad. Actual experience shows that its use is to be recommended notably for excessive corpulence and that the effect is not exhausting to the circulation or to the nervous system. This is probably due to the fact that the water does not interfere to the same extent with the assimilation of the food. Dr. Baumstark of Homburg insists, for instance, that the neutral salts contained in the waters are easily absorbed—that is to say, a portion of the salts are taken up by the blood—therefore the watery evacuations do not contain food products that should be absorbed as nutriment. He argues that physiological action within the body due to the secretions of the glands, the liver, or the mucous membrane of the stomach depends to a large extent on osmosis. This is increased if the blood contains neutral salts such as those provided by the Homburg waters and Dr. Baumstark urges that this would not occur where the salts are of such a nature that they cannot so easily be absorbed.

It would be difficult to find a place where there is such a variety of waters as at *Homburg*. Not only is the result of taking the water free from debilitating effects for the reasons given above but perhaps also because they contain a small proportion of iron. If, however, this does not in itself suffice there are likewise two chalybeate springs.

---

[1] Parts I. and II. appeared in THE LANCET of August 12th (p. 484) and 26th (p. 629) 1905.

The Luisenbrunnen is a mild, easily digested iron water which contains a small quantity of sulphuretted hydrogen but no chloride of calcium. This perhaps explains the fact that it does not excite or produce headaches. Then there is the Stahlbrunnen which contains much more salt and more iron; it is a very strong tonic but does not produce constipation. Thus it is possible to stimulate and to strengthen while ridding the system of superfluous fat. Dr. Fr. Hoeber, in a small book on the waters of Homburg, says that:—

> To sum up, we have seen that saline waters are almost entirely absorbed and that they can diminish the weight of the body because the nutritious substances introduced into the human system are more quickly consumed; but we have also seen that if given in smaller doses they promote the assimilation of albuminates and thus help nutrition and facilitate the reception of nourishing food. In a word, the great advantage of the mineral springs, rich in chlorides and poor in sulphates, is that, according to the will of the physician, they may promote as well the regressive as the progressive metamorphoses of the body, and that according to their administration and the diet observed during their use they can increase or diminish the weight of the body. This is the reason why the Homburg waters have in many cases apparently quite opposite effects; this, too, is the reason why we see here, on the one hand, stout and pasty-looking men relieved from the excess of weight, leaving the place rejuvenated and with recovered elasticity, and why, on the other hand, we see tender and delicate-looking ladies of tall and thin frame returning to their homes with a healthy complexion, firmer in muscles, and increased in weight.

Dr. Hoeber also urges that delicate patients suffering from anæmia or torpidity of circulation who are advised to take the iron waters at St. Moritz or at some other high altitude should first stay, if only for a fortnight, at a bracing place which combines the invigorating effect of dry mountain air with a mild climate, so that the patient may thus prepare himself for the rough and more trying effect of the high mountain resorts. Homburg is about half-way between England and the Swiss mountain stations. Its climate is very dry because the nearest rivers, the Rhine and the Main, are too far off and the brooks in the neighbourhood are too small and shallow for the evaporation of water to produce mist or damp. Then there is very little rain and it is rapidly absorbed by the soil. The neighbouring mountains and vast forests give a low summer temperature and a stimulating atmosphere. It is an admirable half-way house between, for instance, the mild moist climates of the southern coasts of England and the high altitudes and rigorous climate of the Engadine or of Davos.

Dr. C. Weber, who is one of the leading physicians at Homburg, expressed his surprise that there were not more cases of heart disease sent to Homburg: the wells were in such a perfect condition, they were so rich in carbonic acid gas, and it had been often demonstrated that baths in such waters were very useful in diseases due to insufficiency of heart action or to increased tension of the blood (arteriosclerosis). But many patients had been kept away last year by the motor race which was held in June and because in August there were too many gaieties and the cost of living in some of the hotels was too high. Yet no health resort more faithfully fulfilled its promises so far as the efficacy of its waters and baths was concerned. There has been, however, difficulties in regard to diet. Some hotel-keepers did not take an intelligent interest in the patients and did not readily provide the diet prescribed. Though this was often cheaper than the usual hotel fare an extra charge would be made. Now, however, the hotel-keepers are beginning to understand their true interests better. The 15 active practitioners of Homburg have met and after much discussion they agreed upon four dietary tables with three subsections each. These have been drawn up and printed. They are given to the patients and by the patients to the hotel-keepers, and as they are the same, though coming from different medical attendants, the respective cooks are getting familiar with them and know better what to do. The four diet tables are for gout and kindred diseases, for gastric disorders, for chronic obstruction, and for diabetes. These are matters that will be taken in hand more and more carefully by all the hotel and lodging-house keepers as they realise that on the cure of the patients depends the prosperity of Homburg. Therein lies the future of the town.

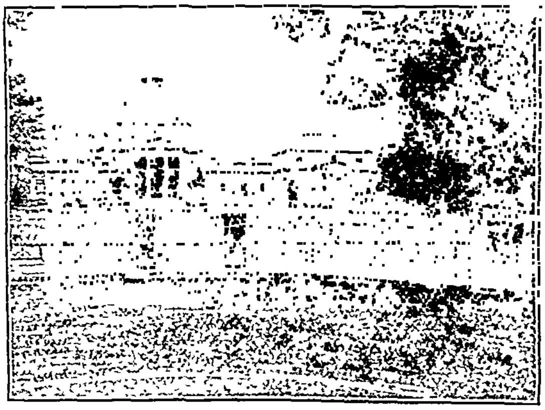
Dr. Weber also pointed out to me the newly introduced thermal-mud treatment. This is sometimes known as the fango treatment. The clay heavily charged with silicate found close to the Homburg springs is dried by exposure to the air and then ground to fine powder. To this hot mineral water is added till a sort of potters' clay is produced. It is then placed like a poultice on the affected limb. The temperature is generally from 115° to 140° F. and being a bad conductor the mud preserves the heat for a long time, so that the mud poultice can be applied for from 25 to 40 minutes. After that the patient stays 15 or 20 minutes in a mineral bath. The following analysis of the Homburg thermal mud has been made by Dr. A. Rüdiger:—

Silica (SiO_2)	37·400
Alumina (Al_2O_3)	13·776
Ferric oxide (Fe_2O_3)	3·612
Lime (CaO)	0·566
Magnesia (MgO)	0·904
Potash (K_2O)	0·526
Soda (Na_2O)	2·820
Sulphuric anhydride (SO_3)	0·290
Chlorine (Cl)	0·310
Organic and volatile substances	4·520
Water	35·276
	100·000

No demonstration has yet been given to show if any of these constituents penetrate and enter the general circulation of the patients, but researches are now being carried forward with a view of ascertaining whether the mud contains radio-active substances. In any case it gives good results in the treatment of several complaints and notably of chronic rheumatism, gouty articular deposits, and pleural and other effusions.

It is at the Kaiser Wilhelmsbad that these mud poultices are to be obtained. This is a palatial building and was constructed in 1890 (see Fig. 1). Here there are 48 separate rooms for the mineral baths. There are also vapour baths, electric baths, a swimming bath, and a room for massage and for gymnastics. For the mineral-water baths the Schwarz method is applied. The bath is made of metal, probably copper or brass. In this the water from the springs is admitted in its natural and cold condition. Had the water been previously heated it would have lost its carbonic acid gas. The temperature is raised at the moment the bath is going to be used by steam coils that pass underneath and outside the bath. Then there are also mud baths. These are made with peat taken from the Rhön mountains, which is torn asunder and reduced to small particles. It is then mixed with the mineral-water and warmed. All this implies the use of machinery and a considerable amount of labour. The baths are luxuriously fitted up, well warmed in the colder months of the year, and an elaborate treatment may be here followed with every comfort.

FIG. 1.



The Kaiser Wilhelmsbad, where the mineral water, mud, and other baths are given. The inclosure in the foreground protects and leads down to the Kaiserbrunnen spring.

Close at hand, in the identical building where the first roulette table was established, there is an institute for mechano-therapeutics. This has been established by Dr. Gustav Hamel, and he has there 35 different machines giving 60 different kinds of movement. Large windows open out on to a broad balcony or terrace with two pine trees growing through the flooring. Beyond a thick cluster of trees hides this from view. When the weather is fine carpets are laid out here and the patients can sit in the open air. Thus as the machines expand their chests and induce deep breathing they absorb the pure out-door air loaded with the balsamic perfume of the pine trees. Dr. Hamel has come to an agreement with the medical practitioners of the town that he will not in any way compete with them. He will not practise medicine in the ordinary sense of the term but will only treat by mechano-therapeutics those patients who are sent to him by the medical practitioners of Homburg.

From all these details it will be seen that the town of Homburg is admirably equipped for the treatment of a large variety of diseases. By nature it is favoured in every way. The money and the art brought to bear by the Blanc brothers have created not only a splendid Kurhaus, with its theatre, its vast concert rooms, and reading rooms, but has surrounded it by a most beautiful park. Here the bands play, here idlers while away their time with golf or tennis, the patients sip the waters, and the more thoughtful may read in the open air in the midst of beautiful scenery (see Fig. 2). From this centre a great variety of paths and roads lead to low hills or to mountains some 3000 feet high. Patients with feeble hearts can here take graduated exercise on level ground or by climbing. Those who have a taste for natural sciences—botany, entomology, geology—can pursue their studies in the Taunus mountains. Though undoubtedly a large proportion of the people who frequent Homburg have more money than brains, still there are a few professors and men of intellect who need the waters. Perhaps it is in the provision of intellectual occupations and diversions that there is the most need for improvement and some innovations. Rambling clubs, for instance, might be established with competent scientific guides to explain something of the botany, zoology, or geology that can be gleaned in the walks and excursions which are so numerous and varied round and about Homburg.

FIG. 2.

View from the Kurhaus terrace of the pleasure gardens and park where the mineral springs are situated.

In a word, the citizens of Homburg must strive to efface from their memories the recollection of the extravagant, reckless, ignorant, wealthy, dissipated crowds that used to fling their money away in the hotels and on the roulette tables. If some such people still come to Homburg it must be borne in mind that they come not to gamble but rather as penitents punished for over-indulgence and seeking to remedy by drinking the waters the evil wrought in the past. Such persons do not want to revert to their former extravagances and if they find themselves surrounded by temptations to this effect then they will go in preference to other health stations that have a better comprehension of their medical mission. Such, then, is the future of Homburg It will become more and more a place where all the inhabitants will grow in the understanding that it is their duty in life to help, each in his particular line, to cure patients coming from all parts of the world. Homburg has no other claim for public patronage than that arising from the number of cures effected. In the past Homburg was a pleasure resort. In the present it suffers from the traditions then created. In the future it must efface those traditions and give itself up wholly to the noble mission of placing its great natural resources at the service of suffering humanity.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Infants in Elementary Schools.

THE feeling against children under five years of age being allowed to attend the public elementary schools seems to be spreading. The medical officer of health of Bradford says that from three to five years is the age when children are most susceptible to measles and when it is most fatal. If they were not allowed to attend school under five years of age there would be a smaller mortality from this disease and from whooping-cough, less defective eyesight, and more room for older pupils. The medical officer of Oldham takes much the same view and also says that school life, especially among the infants, is greatly responsible for the prevalence of certain infectious diseases. The chairman of the Barrow education committee says that the exclusion of these children from school would lessen the cost of education by £2000, a sum equalling a rate of 2*d.* in the £. At a recent meeting of the Sunderland education committee it was decided by 18 against 2 not to admit children under five years of age. The chairman said that the schools ought not to be used as crèches, while another member "deplored the continual weakening of parental responsibilities" and said that it was not the ratepayers' duty to provide nurseries for infants, although infants might be in some ways far better in school than in the slums. If the mothers were free to give proper attention to the children, if they were wishful and sufficiently instructed to look after them properly, they would be the right people to have charge of their own children, but take the average of poor women in the "mean streets" and the slums and one could scarcely contend that the children would be better at home than at school, considerations of epidemic disease apart.

Railway Ambulance Work.

On August 24th, at the London-road station, Mr. E. Chapman, M.P., presented the Royds Ambulance Shield to the Newton Hyde team, the winners of the annual competition. The shield is the gift of Colonel Royds, M.P., and is competed for yearly by teams representing the various depôts on the Great Central Railway. With the shield is given a money prize of £5, the second and third teams receiving £3 and £2 from the Sir Edward Watkin Meritorious Conduct Fund. The second team this year was the Hull and the third the Barnetby (engineers' department). There are already more than 1000 servants of the company competent and ready to render first aid to the injured. The movement has grown rapidly and is still growing. Six years ago only three teams competed for the Great Central prize, while this year there were 18. This movement deserves every encouragement. It is an indication of kindliness and humane feeling on the part of the men, which the instruction converts into a practical, skilled, and disciplined agency for good, while the morally elevating effect on the men is by no means the least of the benefits that this ambulance work brings in its train.

The Grocer's Mistake.

One of those unfortunate little mistakes which cause death was inquired into by the Manchester county coroner on August 23rd. A woman in Gorton went to a grocer's shop for some castor oil. By mistake she was served with camphorated oil instead, and after drinking it was taken ill and died. When the grocer found out his mistake he ran to her house and said he had given her the wrong oil, but when told she had taken it he added that it would do her no harm. She died shortly afterwards. Mr. G. A. Wolfendale, who made a post-mortem examination, said there were traces of the oil in the stomach. His opinion was that death was due to cardiac syncope, accelerated by irritation of the stomach, due to the presence of camphor. Mr. W. B. Rigby agreed in the main with Mr. Wolfendale's evidence, but thought the fatty condition of the heart was sufficient to cause death. He said there seemed to be none of the symptoms of camphor poisoning. "There would be an intense burning of the throat," he pointed out, but the deceased did not complain of such pain. He rather thought, however, that death had been accelerated by the camphor. The camphorated oil would probably cause much less burning in the throat than camphor dissolved in spirit. The verdict was death by misadventure, and the coroner advised the grocer to be more careful in future. No doubt he will be, but such accidents are too frequent and show that the sale of poisons is often left in unsafe hands.

Hospital Sunday and Saturday Fund.

The amount collected for the Hospital Sunday and Saturday Fund in Manchester and Salford allows this year for the distribution of £7500 among the various medical charities. The apportionment is as follows:—

	£	s.	d.		£	s.	d.
Children's Hospital	1243	3	2	Hospital for Skin Diseases	145	17	2
Royal Infirmary	1215	13	9	Ear Hospital	54	15	4
Sick Poor and Private Nursing Institution	737	2	2	Christie's Hospital (Cancer Pavilion)	81	1	10
Hospital for Incurables	521	15	11	Victoria Dental Hospital	61	11	3
Salford Royal Hospital	523	8	9	Holme Dispensary	52	6	11
Ancoats Hospital	499	12	2	Lock Hospital	43	10	4
Southern and Maternity Hospital	433	19	8	Chorlton-on-Medlock Dispensary	25	17	6
Royal Eye Hospital	457	2	0	Homœopathic Institution	8	11	10
Northern (late Clinical) Hospital	431	15	11				
St. Mary's Hospital	414	15	4				
Hospital for Consumption	343	13	9		£7500	0	0

Pure Milk for Leeds.

An experiment is to be tried at Leeds which will be watched with interest. An establishment for the supply of pure milk, run at a loss, is to be opened. It is in the heart of Leeds, surrounded by the poor, is the property of the corporation but the expenses of the scheme are being borne by a voluntary fund to which the Lord Mayor has contributed. The provision of pure milk direct from the farm, if carried out successfully, will be a priceless boon, but it would be unfortunate if what looks like the element of charity in the scheme should do anything to sap the sense of responsibility and the self respect of the parents.

Suicide Epidemic.

Manchester and the district around have had to chronicle an unusual number of suicides lately. A Salford publican 29 years of age, who was slightly in debt, from which he could easily have been extricated, was found with his throat cut and "on a barrel was found a bottle and a tumbler containing ammonia." In the same district a commercial traveller shot himself because an appointment which he expected had been deferred, while he had, it seems, some hallucinations or fancies about his health. The verdict was, of course, "temporary insanity," but the unfortunate man had arranged his affairs in a letter to the coroner and expressed a wish to be cremated. Another case was that of a man, aged 71 years, who had been in an asylum and whose relatives had been cautioned as to his being suicidal. He was found in a claypit. The jury added a rider to the verdict to the effect that he ought to have been more closely attended, but medical men with experience in the care of suicidal patients know that no amount of attention will ever avert such catastrophes. These cases were the tragedies of one week end.

Sept. 4th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Hospital News.

BY the will of Mrs. John Ponca of Erdington several charitable institutions benefit. I understand that the Birmingham General Hospital and the Queen's Hospital will each receive £10,000.—Arrangements are being made for the opening in connexion with the Guest Hospital and Dudley Dispensary of a branch for the treatment of diseases of the eye. The branch will be maintained by a special fund and the in-patients will be treated at the Guest Hospital while the out-patients will go to the dispensary. The patients will be under the care of Mr. B. H. St. Clair Roberts.—At the last meeting of the Hanley, Stoke, Fenton, and Longton joint hospital board a letter was read from the Local Government Board sanctioning the borrowing of £1334 for the provision of a new mortuary and water storage tank at the hospital. The letter proceeded to state that the Board regretted the decision of the joint board not to provide accommodation for enteric fever. It pointed out that enteric fever was in the majority of cases a far more formidable disease than scarlet fever, that the mortality caused by it was greatest among persons in the prime of life, that the chances of recovery of the patient depend largely upon his receiving proper nursing and diet; and that infection frequently spread from one member of a family to another under the conditions of accommodation and nursing which were met with in households of the poorer classes. The Board found from the reports of the Registrar-General that in the Stoke registration district, which corresponded with the area of the joint hospital district, in the five years ending 1904, 174 deaths from enteric fever were registered against 149 from scarlet fever. It appeared to the Board, therefore, that in reserving its hospital for scarlet fever and diphtheria, to the exclusion of enteric fever, the joint hospital board was not making the best use of the accommodation which it possessed in the health interests of the district. Replying to a question, Dr. C. H. Phillips said that the number of patients in the hospital had never exceeded 120, whereas the accommodation was about 160 beds. He suggested that they should use one 24-bed pavilion for cases of enteric fever and he thought that they would have sufficient accommodation for other cases. It was decided to refer the matter to the chairman's consulting committee for further consideration. During the quarter 103 patients had been admitted into the hospital—viz., 46 suffering from scarlet fever, 55 from diphtheria, and six from combined diseases. Nine deaths had occurred from diphtheria and two from combined diseases.—The annual meeting of the supporters of the Corbett Hospital, Stourbridge, has recently been held. During the year 624 cases had been examined and 355 patients had been admitted to the hospital. The hospital premises have been enlarged by the addition of a sterilising chamber. The medical officers in their report state that the demands on the resources of the hospital have so increased that they regret their inability to cope with them. They wish to see not merely increased accommodation for patients but the establishment of a convalescent home in the country to which patients could be sent from the hospital. The financial report shows that while the income is practically unchanged there had been last year £350 less expenditure.

The Small-pox Epidemic at Nuneaton.

Another outbreak of small-pox has occurred at Nuneaton, the second this year and the third within 18 months. The outbreak is traced by the medical officer of health to a schoolboy, but where the lad contracted the disease he has been unable to find out. The number of cases notified up to the present is 40 and of these only three were vaccinated. The outbreak has been almost entirely confined to children, only three adults having been affected. No less than 19 cases were attributable to the schoolboy who seems to have initiated the epidemic. All possible precautions are being taken by the medical authorities to limit the spread of the infection. A house-to-house visitation is being energetically made throughout the affected area by a county council health visitor and a school attendance officer. The vaccination officer acting under instructions of the board of guardians is also visiting each house and vaccinating the inmates. The workhouse is closed except to urgent cases and inmates' leave of absence is suspended. No visiting is allowed at the General Hospital and the public open-air bath has been closed. The sanitary committee of the district council has decided to remove the sand from a pit in the Nuneaton recreation ground where many of the children down with small-pox had been in the habit of playing. Unfortunately difficulties have been put in the way of the medical authorities by parents not merely neglecting to notify cases but wilfully suppressing all information about them. Cases have been brought to their notice by anonymous communications and their work, in consequence of the great difficulty they have experienced in unearthing cases, has literally occupied them night and day. Police proceedings have been taken in several instances and fines summarily inflicted. Luckily the epidemic is a mild one, only two cases, so far, being of the confluent variety.

Birmingham and Day Nurseries.

Now that the local educational authorities have discretionary power to refuse the admission of children under five years of age to their schools, attention is being directed to the question of creches or day nurseries for such children. Many of the schools in Birmingham have been specially adapted for the reception of small children and it is probable that for some time at least children under five and over three years of age will not be excluded. There are already two creches in Birmingham, the result of philanthropic effort, and although small, being only able to accommodate an insignificant proportion of the infant population in the immediate district in which they are situated, they have done, and are still accomplishing, a valuable work. The advantages offered are readily sought and evidence is not wanting to show that there would be a real demand for such provision if made in the most congested and poorest quarters of the city where oftener than elsewhere women are the bread-winners. The subject was referred to by the medical officer of health in a special report last year, but without his making any recommendation. It has also been brought before the health committee, but no action has as yet been taken. In view of the infantile mortality and the decreasing birth-rate many in Birmingham think that some such provision should be made, but the general feeling is that it should emanate from a private rather than a public source. The question may, in the near future, reach a more acute stage in Coventry than in Birmingham, for the Coventry city council has confirmed the recommendation of the sanitary committee that the education committee, in view of the extensive prevalence of infectious disease in infants' schools during the last few years and on the grounds of the general health of children, should be urged to do its utmost to discourage the attendance of children under the age of five years at its schools.

The Royal Commission on the Care and Control of the Feeble-minded.

At the last meeting of the Stoke-on-Trent board of guardians a letter was received from the Local Government Board stating that the Royal Commission on the Care and Control of the Feeble-minded had appointed two medical men to make an inquiry respecting the number of the mentally defective in the union of Stoke and in several unions of Somersetshire. Dr. W. A. Potts of Birmingham will make the inquiry in the Stoke-on-Trent union. The inmates of the Poor-law institutions, workhouses, infirmaries, casual wards, and schools will be examined with a view of noting and classifying the mentally defective therein. Inquiries will also be made from medical officers and relieving officers as to the same classes comprised among those receiving out-relief.

The Health of Worcester.

The medical officer of health of Worcester in his report upon the second quarter of the year records that the birth-rate of 24·22 per 1000 of the population was 3·3 per 1000 below the average rate of the ten preceding second quarters, while the death-rate of 13·85 was 4·21 per 1000 less than the average of the ten preceding quarters. The deaths of infants under one year numbered 51, which had only been once exceeded during the ten preceding second quarters and was ten in excess of the average number. The infantile death-rate per 1000 births was 4·5 above the average.

Sept. 5th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Report of the Medical Officer of Health for the Year 1904: Health of Liverpool.

THE area of the city comprises 14,909 acres, or a little more than 23 square miles, with an estimated population of 723,430. The birth-rate continues high—namely, 33·5 per 1000 of the population. A diagram in the report shows how the birth-rate of Liverpool has exceeded that of England and Wales during the last 40 years. The death-rate of the city for the year was 21·9 per 1000 of the population, being 2·1 per 1000 higher than that of the preceding year. The increase in the death-rate was entirely owing to the increase in deaths of infants and children below five years of age, the deaths at other age-periods having been below the average. The year 1904 was characterised by an excessive mortality from infantile diarrhœa during the months of July, August, and September, the temperature being very high in July and the rainfall lower than the average during that and the preceding month. The deaths of over 1500 infants during July, August, and September were registered as being due to choleraic diarrhœa and allied causes. Great attention has been given to the milk depôts. The members of the medical staff of the Children's Infirmary and other medical men of the city have made use of the depôts as a means of lessening sickness amongst infants requiring their attention. The more dangerous forms of zymotic disease have shown a decrease. Representatives of the health committee were invited by the London County Council to attend a conference upon the subject of the spread of small-pox by vagrants and the preventive or remedial measures to be adopted. Alderman Roberts and the medical officer of health (Dr. E. W. Hope) attended the conference on behalf of the committee on Nov. 10th, 1904. The conference, which was somewhat prolonged, resulted in resolutions being passed as to the detention, cleansing, and vaccination of tramps. Ultimately these matters were referred to a subcommittee, upon which Alderman Roberts was selected to represent the city of Liverpool. Typhus fever has continued to appear from time to time, although to a relatively trifling extent as compared with its prevalence in former years. With regard to tuberculosis some interesting tables will be found in the report illustrating the remarkable decline in pulmonary tuberculosis owing to the sanitary measures adopted during the last 20 years. The voluntary notification of pulmonary tuberculosis by the medical attendant originated in 1901 has been persevered with and the help of the sanitary authority has thus been available in those forms of the disease in which it can be of use. Instructions for the guidance of tuberculous persons are issued through proper channels. Owing to the prevalence of infectious sickness of various kinds amongst the pupils it was found necessary from time to time during the year to close a considerable number of schools. The greatest sufferers were those attending the infants' schools and the babies' classes. It is not in the interests of health for very young children to be sent to school. On the contrary, there is every reason to believe that injury results from the proceeding. A large number of schools were examined under the terms of the resolution of the education committee, which occupied a considerable amount of the time of the staff. Reference is also made to the working of the Midwives Act. The health committee approved of an application being made to Parliament for additional powers in regard to certain important sanitary measures, notably to facilitate dealing with nuisances and conditions injurious to health arising from noises made by animals in confinement; to prevent the continued occupation of cellar dwellings; for checking the spread of ringworm and for the sanitation of hairdressing saloons; for dealing more effectively with stables; for the better lighting, ventilation, and cleanliness of restaurants and places where food is prepared for consumption; for improved sanitary conveniences in lock-up shops; and for checking nuisance arising from smoke from steamers on the river, hitherto not under control. From time to time considerable anxiety was occasioned by the difficulties in the way of dealing adequately in the interests of the public health with certain parts of the area of the Rivington watershed. The section of the watershed known as the Lever Park threatens to be a source of danger to the community of Liverpool and will require careful consideration to insure the protection of the community from conditions which in almost innumerable instances have been proved to be the source of dangerous outbreaks of typhoid fever. The President of the Local Government Board received a deputation on May 13th, 1904, on the subject of a quinquennial census. Dr. R. Caton and Dr. Hope represented the health committee of Liverpool upon the deputation. The deputation, which was a very large one, represented generally the sanitary interests of the country and was unanimous in urging upon the President the necessity for a quinquennial census. From the report of the medical officer of health for the week ending August 26th, 1905, it is gratifying to know that Liverpool is steadily improving in its health conditions. During the week only 280 deaths were registered, showing a decrease of 130 on the corresponding week of last year, and representing a death-rate of 19·9 per 1000 of the population. The number of births during the same period was 497, being equivalent to a rate of 35·3 per 1000. Only 233 cases of zymotic disease were reported and the deaths therefrom numbered 97, as compared with 209 from the same cause last year.

A New Department at the David Lewis Northern Hospital.

A new department for "orthopædic gymnastics and massage" has been created at the David Lewis Northern Hospital, to which Dr. W. H. Broad (who is devoting himself specially to the practice of massage after a course of instruction in Sweden) has been appointed surgeon in charge. Through the generosity of Mr. Levy, one of the David Lewis trustees, a room has been fitted up at the hospital containing several "exercise machines."

Conference of Lancashire and other Unions.

A conference of representatives of Lancashire, Westmorland, Cumberland, and Cheshire Poor-law unions was held on Sept. 1st in the town hall, Lancaster, under the presidency of Sir John T. Hibbert who quoted statistics showing the increase of vagrancy in the North-western Poor-law district. The meeting favoured the establishment of farm and labour colonies for the accommodation of tramps and a committee to be appointed from the different boards of guardians to further such a scheme was approved of.

The Spread of Asiatic Cholera.

The customary strict precautions taken by the port sanitary authorities of Liverpool are never relaxed and are efficient for dealing with any situation which might arise. The flow of cases of cholera is from east to west and in the opinion of Dr. Hope, the medical officer of health, the first point of difficulty in England will be Hull.

Beri-beri in Liverpool.

The German steamer *Forsteck*, which arrived in the Mersey on Sept. 2nd, had on board five Chinese sailors who were said to be suffering from beri-beri. All were removed to the tropical diseases ward of the Royal Southern Hospital.

Sept. 5th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Newcastle-upon-Tyne: Opening of New Nurses' Home.

THE first stage in the opening of the new infirmary at Newcastle took place when the new nurses' home was recently started. It is now many years since the old infirmary ceased to be able to house its nurses and the majority of them have been sleeping out in the old nursing home, but even this accommodation was insufficient and some had to be lodged in the hostel of the Young Women's Christian Association. The new home has accommodation for 104 nurses, but at present it is only partially occupied, the sisters still retaining their rooms in the old building. In the new home each nurse has a bedroom to herself and these are very tastefully and substantially equipped. The sitting and dining rooms are on the ground floor; they are large, light, airy, and properly furnished. The new infirmary is connected to the home by a covered way, the entrance to the latter being through a large conservatory which will form a very useful addition to the recreation room. Throughout the building the electric light is fitted and a lift connects the various floors in addition to the staircases. Already the place has lost its dreary aspect, for apart from its being inhabited the shrubs and planted borders round about are looking quite smart. The nurses themselves are thoroughly satisfied with their new quarters though at present it means that they have a walk of about 20 minutes night and morning through a not very salubrious part of the town, for the home is about three-quarters of a mile from the old infirmary. They have to make an early start, as breakfast is ready at 6.15 A.M. and they must be on duty by 7. In the evening they reach the home about 9.30 and the lights have to be out by 10.30. Sir Riley Lord, the chairman of the building committee, presided at the opening and was supported, among others, by the Mayor of Newcastle (Alderman J. Baxter Ellis), the Sheriff of Newcastle, Lord Armstrong, Sir George Hare Philipson, Dr. D. Drummond, and Dr. G. H. Hume. The chairman, on behalf of the building committee, officially handed over the home to Lord Armstrong who, as chairman of the management committee, represented that body. At the close of the proceedings the Mayor gave a donation of £5 towards furnishing the nurses' library.

Sunderland Infirmary: Appointment of Honorary Physician; Annual Report.

By the death of Dr. James Murphy two vacancies were virtually caused in the staff of the infirmary, for Dr. William Robinson, who was appointed to the vacancy in the surgical side, was himself one of the honorary physicians. There were four candidates for the vacancy on the medical side—Dr. G. B. Morgan, jun., Mr. A. Ayre Smith, Dr. H. K. Wallace, and Dr. J. Chalmers. The first vote was as follows: Dr. Morgan, 17; Dr. Chalmers, 12; Dr. Wallace, 3; and Mr. Smith, 2. Another vote resulted as follows: Dr. Morgan, 18; and Dr. Chalmers, 16. Dr. Morgan was therefore elected. The 111th report of the Sunderland Infirmary shows that a total number of 11,333 patients were treated at the hospital during 1904, an increase of 606 over those treated in 1903. Of this number 3172 were in-patients and 8161 out-patients. The average stay in hospital was 21 days and the cost per head was £2 18*s.*, while the cost per bed occupied works out at £49 14*s.* 11*d.* The ordinary income, though increased to £10,623, as compared with £10,279 for the previous year, does not quite reach the total expenditure. Funds are not yet forthcoming for the provision of a children's hospital in connexion with the infirmary, though several substantial donations have been received. It seems a great pity that a hospital in which so much work is done does not give more details of its labours, for there is not one word in the report as to the nature of the medical work done nor is there any information that would be interesting to the student of vital statistics.

Central Midwives Board: Newcastle Centre.

At the recent examination held in the Lying-in Hospital at Newcastle-upon-Tyne there were nine candidates of whom two were unsuccessful. The training of the candidates is carried on at the Lying-in Hospital where the nurses attend personally 20 cases, mostly, of course, in the extern charity. Last year there were 800 cases attended and this number is yearly increasing, for there is no other similar charity in the neighbourhood.

Sept. 5th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Infants' Milk Depôt in Glasgow.

A DEPÔT for the preparation of milk suitable for infants was opened in Glasgow in June, 1904. It has been in operation for a year and a report on the work done during the first six months is now published. The milk is getting into the hands of that section of the people whom it is desired to reach and now the dairymen in various localities in consequence of the demand are applying for the specially prepared milk in greater measure than the institution is able to supply it. These dairymen are all anxious to become distributors. The charges for a supply of this milk are payable in advance and the terms are for infants under three months 2*d.* per day, under six months 2½*d.* per day (six-ounce bottles), and over six months 3*d.* per day (seven-ounce bottles). The central depôt is open from 11 A.M. to 6 P.M. on week days and a two days' supply of milk is given out on Saturdays. The milk is supplied in bottles in a basket, each bottle containing sufficient milk for one meal, the amount varying with the age of the child. Infants under two months of age receive nine bottles per day, while older children receive fewer bottles as they are fed less frequently. Breakages are charged at the rate of 1*d.* per bottle and damages to the baskets must be made good. Every person using the milk is supplied with a teat and mothers are warned that on no account must a bottle be opened until the infant is ready to be fed. It is impressed upon the parents that the milk must never be used in preference to that of a healthy mother, which is the best of all foods for young infants. A leaflet is also issued to the purchasers bearing instructions as to the hours of feeding, the heating of the milk, and the cleansing of the bottles after use. During the first six months 314 cases were entered at the depôt, and of these at the end of that period 176 remained on the register. Of those who did not continue taking the milk 44 children left within a week's time, 11 within two weeks, 14 within four weeks, 18 continued till the third month, 11 to the fourth month, and five over four months. It is satisfactory to note that a large majority of the children are in the early months, 84 of the total being under a month at entry, and 54 being under two months. As was to be expected, the largest proportion of the children is drawn from the districts in the immediate neighbourhood of the depôt, but with the increase in number of the distributing dairies those living at a greater distance should have no difficulty in obtaining a regular supply of the milk. Up to the end of December, 1904, only two distributing dairies in addition to the depôt were in operation, but at the date of writing there are nine such distributing centres. At the depôt a register is kept containing a carefully prepared record of the essential facts appertaining to each child. Some difficulty has been found in obtaining information regarding those who are supplied through the distributing dairies but in this respect much valuable assistance has been given by the Charity Organisation Society in the visitation of households to which milk is being sent. This is regarded as a most essential part of the work if it is to have any educational value. As the value of this institution becomes more recognised by that section of the people for whom it is intended it is to be expected that a change for the better will take place in the infantile mortality in the city.

The Dangers of Shellfish.

In the early part of the summer the medical officer of health of Glasgow issued a report dealing with the dangers of eating shellfish gathered from infected areas of the shore and especially warning trippers who, from ignorance, were likely to be the worst sinners. Such a warning was not given needlessly, as is evident from the fact that during the last fortnight in Glasgow six cases of enteric fever, due to the eating of raw mussels, have been reported. In four of the cases the shellfish were gathered at an east coast town and in the other two at a Clyde watering-place.

Dunoon Cottage Hospital.

This hospital has been in existence for 20 years and in that time it has done excellent work. Owing to the increase of population in the district it was found that the hospital could not meet all the demands made on it. A bazaar has been held to raise funds for the hospital and the directors were fortunate in getting Princess Louise to open it. The sum aimed at was £4000. The amount realised by the bazaar was £2909 12*s.* 4*d.* and this with a donation of £1000 from Mr. Younger of Benmore and £500 from Mr. Coats of Paisley makes a total of £4409 12*s.* 4*d.* The directors have not decided whether they will extend the present hospital or rebuild on another site.

Salaries of Dispensary Medical Officers

THE inquiry recently conducted by Sir Acheson MacCullagh, Local Government Board inspector, into the salaries of the medical officers of the Tullamore union was one of more than usual interest. A consensus of opinion was expressed by the guardians that the present salaries were inadequate and that a suitable increase in them was debarred by Clause 6 of the Amending Act to the Local Government Board Act. That clause provides that any increase given to the medical men over the salaries they receive in what is known as the standard year should be borne altogether by the local ratepayers. It was said that this clause was rushed through Parliament and Mr. J. S. McArdle of Dublin, who attended the general meeting of the Irish Medical Association at Killarney, said that it was the chief obstacle in the settlement of suitable salaries for the dispensary medical officers. In the ordinary course the Treasury would defray half the amount of any increase and if this was done the Poor-law guardians would pay the remaining half. Now they cannot afford to do so. Mr. G. A. Moorhead, who has practised in that district for many years, deposed on oath that £100 per year went in connexion with his official duties, leaving him £50 and the emoluments of his practice to live upon. The other medical officers of the union gave similar testimony and at the conclusion of the meeting a resolution was passed that under the existing conditions—inadequate salary, absence of promotion, and uncertainty of pensions—it was impossible to attract the best men to the Irish Poor-law medical service.

Belfast District Lunatic Asylum.

Dr. W. Graham has just published, as resident medical superintendent, the seventy-fifth annual report of the Belfast District Asylum for the year ending Dec. 31st, 1904. The total number of patients under treatment was for the 12 months 1325—that is 633 males and 692 females. There were 100 deaths and 154 discharges and the admissions showed an increase of 12 as compared with the previous year. 79 patients were during the year transferred from the Belfast workhouse, making a total of 673 received from that institution during the past seven years. Dr. Graham says:—
